```
# This Python 3 environment comes with many helpful analytics libraries installed
# It is defined by the kaggle/python Docker image: https://github.com/kaggle/docker-python
# For example, here's several helpful packages to load

import numpy as np # linear algebra
import pandas as pd # data processing, CSV file I/O (e.g. pd.read_csv)

# Input data files are available in the read-only "../input/" directory
# For example, running this (by clicking run or pressing Shift+Enter) will list all files under the input directory

import os
for dirname, _, filenames in os.walk('/kaggle/input'):
    for filename in filenames:
        print(os.path.join(dirname, filename))

# You can write up to 20GB to the current directory (/kaggle/working/) that gets preserved as output when you create a version using "Save & Run All"
# You can also write temporary files to /kaggle/temp/, but they won't be saved outside of the current session

# Use the kagglehub client library to attach Kaggle resources like competitions, datasets, and models to your session
# Learn more about kagglehub: https://github.com/Kaggle/kagglehub/blob/main/README.md

import kagglehub
# kagglehub.dataset_download('<owner>/<dataset-slug>')
```

```
/kaggle/input/datasets/mdshahrirhabib/new-yelpdata-train/new_data_train.csv
/kaggle/input/datasets/mdshahrirhabib/new-yelp-data-test/new_data_test.csv
```

0    1212
Name: count, dtype: int64
```

First, both the train set and the test set have the same 22 variables and data types, which is what we want. In both sets, the goal is very close to being equal: training is 4,994 vs. 4,935, and testing is 1,212 vs. 1,271. Since this scenario is not a very important case of class mismatch, we shouldn't use oversampling or class weights immediately.

Next, there isn't much missingness. Some values for reviewContent and location are missing in training, but not in testing. In testing, two values for location are absent but not review text. These three training rows will need extra attention later because reviewContent is important for all text-based models. But we shouldn't drop them yet; we need to check them out first.

The dates are still saved as objects, not as real datetime variables. At this point, that's fine. We will change the date and yelpJoinDate later so that we can look at time trends, the age of reviewer accounts, and any possible leaks.

A.2 Inspect examples from both target classes

In [10]:
```
# Inspect examples from both target classes

print("FLAGGED = 0")
display(
    train.loc[
        train["flagged"] == 0,
        ["reviewID", "reviewContent", "rating", "reviewerID", "reviewCount", "friendCount"]
    ].head(10)
)

print("\nFLAGGED = 1")
display(
    train.loc[
        train["flagged"] == 1,
        ["reviewID", "reviewContent", "rating", "reviewerID", "reviewCount", "friendCount"]
    ].head(10)
)
```

```

From these examples, flagged = 1 appears to correspond to fake / filtered / suspicious reviews, while flagged = 0 appears to correspond to genuine / recommended reviews. That interpretation is also consistent with the Kaggle version of this dataset, which describes the labels as Genuine = 0 and Fake = 1.

Your sample supports that interpretation. Many flagged = 1 reviewers have very low review counts and friend counts, whereas several flagged = 0 reviewers have more established reviewer histories. That pattern also aligns with prior Yelp fake-review research, where filtered reviews are treated as fake and unfiltered/recommended reviews as genuine or near-ground-truth labels.

But we should write this carefully in the dissertation. Yelp's labels are not perfect human-verified truth; they are derived from Yelp's filtering/recommendation system, so they are better described as proxy or near-ground-truth labels rather than unquestionable ground truth.

So for our analysis, we can now define:

0 = Genuine / Recommended

1 = Fake / Filtered / Suspicious

A.3 Duplicate and Train/Test Leakage Audit

In [11]:
```
# 1. Duplicate complete rows
print("Duplicate full rows")
print("Train:", train.duplicated().sum())
print("Test :", test.duplicated().sum())

# 2. Duplicate review IDs
print("\nDuplicate review IDs")
print("Train:", train["reviewID"].duplicated().sum())
print("Test :", test["reviewID"].duplicated().sum())

# 3. Duplicate review texts within each dataset
print("\nDuplicate review content")
print("Train:", train["reviewContent"].duplicated().sum())
print("Test :", test["reviewContent"].duplicated().sum())

# 4. Same review IDs appearing in BOTH train and test
common_review_ids = set(train["reviewID"]) & set(test["reviewID"])
print("\nReview IDs shared between train and test:", len(common_review_ids))

# 5. Same review text appearing in BOTH train and test
train_text = set(train["reviewContent"].dropna())
test_text = set(test["reviewContent"].dropna())

common_review_text = train_text & test_text

print("Review texts shared between train and test:", len(common_review_text))
```

```
# Show overlapping texts if any
if len(common_review_text) > 0:
    overlap = pd.DataFrame({"reviewContent": list(common_review_text)})
    display(overlap.head(20))
```

```
Duplicate full rows
Train: 0
Test : 0

Duplicate review IDs
Train: 0
Test : 0

Duplicate review content
Train: 12
Test : 1

Review IDs shared between train and test: 0
Review texts shared between train and test: 3
```

	reviewContent
0	love it
1	yum
2	a

A leakage audit identified three identical review texts shared between the predefined training and test sets. Although these overlaps consisted only of extremely short generic reviews ('love it', 'yum', and 'a'), they were removed from the final evaluation set to ensure strict train-test independence.

A.4 Inspect duplicated review texts in TRAIN

In [12]:
```
# Inspect duplicated review texts in TRAIN
train_dupes = train[
    train["reviewContent"].duplicated(keep=False)
].sort_values("reviewContent")

A.5 Duplicate text length audit

In [13]:
```
train_dupes = train[
    train["reviewContent"].notna() &
    train["reviewContent"].duplicated(keep=False)
].copy()

train_dupes["word_count"] = (
    train_dupes["reviewContent"]
    .str.split()
    .str.len()
)
```

```
duplicate_summary = (
    train_dupes
    .groupby("reviewContent")
    .agg(
        occurrences=("reviewID", "count"),
        word_count=("word_count", "first"),
        unique_reviewers=("reviewerID", "nunique"),
        unique_restaurants=("restaurantID", "nunique"),
        unique_labels=("flagged", "nunique")
    )
    .sort_values(["word_count", "occurrences"], ascending=[False, False])
)

display(duplicate_summary)
```

reviewContent	occurrences	word_count	unique_reviewers	unique_restaurants	unique_labels
i always enjoyed asian cuisine especially vietnamese i going simply it restaurant lincoln belden the food healthy light delicious while dining in i noticed restaurant offering cooking class i board the class took place monday thirteenth 5 30 pm i never much enthusiastic student soon greeted charisma joy i actually looking forward class though i felt like i convention gave us name tags actually helped bring whole class together wine beer soda others provided accompany food going indulge we introduced chef kim class started she well spoken attentive class answering questions people thinking about after dish kim interacted us making sure everything clear first came lesson spring rolls kim started introducing peanut dipping sauce followed actual spring rolls one high lights evening probably rolling spring rolls i mention size spring roll probably diameter fat cuban cigar the tamarind shrimp soup next learning dish it interesting learn tamarind fruit plant since i never heard night then came simply beef one favorite dishes restaurant i really excited learning make it the teaching dish done chef hung his explanations briefed short fortunately kim follow extend answers explanations after fabulous class came best anticipating part everyone waiting for eating food after seeing actually went every dish made appreciate much food it felt like every taste bud assigned specific ingredient making every bite pleasent this whole experience amazing i met new people learned cook one favorite dishes got eat really good food i would definitely again as matter fact another class june barbequing time show family friends summer gatherings	2	254	2	1	1
milk honey decent breakfast i feel they re bit overpriced food s so so good pastries especially cookies my favorite restaurant area picante though they freshest organic food find reasonable prices they re open late	2	35	2	1	1
not sure review posted i like place much i wanted repost it	2	12	1	2	1
good food	2	2	2	1	1
great food	2	2	2	2	1
great pizza	2	2	2	2	1
delicious	4	1	4	4	2
excellent	2	1	2	2	1

There are three different types of similar information. There are clear substantive duplicates between the long 254-word review and the short 35-word review. Each shows up twice, from different users, for the same place, with the same title. Those are much more likely to be copied or repeated content than to be happen by chance. The 12-word review is also repeated, but it's interesting that the same reviewer wrote it for two different restaurants. This could mean that the text was reposted or used again. Short phrases like "good food," "great food," "great pizza," "excellent," and "delicious" are all different, but it's natural for them to use the same words.

Exact duplicate review texts of more than 10 words will be treated as substantive duplicates and investigated separately. Very short repeated phrases will be retained because identical expressions can plausibly occur independently across reviewers. Any exact text appearing in both training and test sets will be removed from the held-out test set to preserve strict independence.

A.6 Missing-value record inspection

In [14]:
```
print("TRAIN — missing reviewContent")
display(
    train[train["reviewContent"].isna()][
        [
            "reviewID", "reviewerID", "restaurantID",
            "flagged", "rating", "reviewCount",
            "friendCount", "ReviewLength"
        ]
    ]
)

print("\nTRAIN — missing location")
display(
    train[train["location"].isna()][
        [
            "reviewID", "reviewerID", "restaurantID",
            "flagged", "rating", "reviewContent"
        ]
    ]
)

print("\nTEST — missing location")
display(
    test[test["location"].isna()][
        [
            "reviewID", "reviewerID", "restaurantID",
            "flagged", "rating", "reviewContent"
        ]
    ]
)
```

```

Review of the three missingOnly 3 out of 9,929 training observations are content records, which is less than 0.03%. One is marked as real (flagged = 0), and the other two are marked as suspicious or fake (flagged = 1). Getting rid of them would not have much of an effect on the class balance. Text-based models can't use records that don't have review text, which is even more important. Because of this, I think that these three rows should only be taken out of the modeling copy for the final modeling dataset. The raw dataset should stay the same.

But there's something strange: all three rows of lost text have ReviewLength = 1. If there is no information in the review, why is its length listed as 1? Before we use ReviewLength as a feature, we should check how it was calculated. This is the kind of small problem with the quality of the statistics that we decided not to ignore.

When it comes to location, there is only one lost number in training and two in testing. All three have been marked as fake, but since there are only three of them, we can't say that missing locations are linked to fake reviews. More seriously, I don't think location should be used as a predictive tool right now. It has a high heart rate, might make the model learn geography-specific artifacts instead of lying, and isn't essential to your suggested detection scheme. Because of this, it's likely that we won't need to infer these three places at all.

A.7 Validate the Review Length variable

In [15]:
```
# Calculate word count directly from the available review text
train["calculated_word_count"] = (
    train["reviewContent"]
    .str.split()
    .str.len()
)

test["calculated_word_count"] = (
    test["reviewContent"]
    .str.split()
    .str.len()
)

# Compare supplied ReviewLength with our calculated word count
print("TRAIN — ReviewLength comparison")
print(
    train[["ReviewLength", "calculated_word_count"]]
    .describe()
)

print("\nTEST — ReviewLength comparison")
print(
    test[["ReviewLength", "calculated_word_count"]]
    .describe()
)

# Count exact matches and mismatches
train_valid = train["reviewContent"].notna()
test_valid = test["reviewContent"].notna()

print("\nTRAIN")
print(
    "Exact matches:",
    (
        train.loc[train_valid, "ReviewLength"]
        == train.loc[train_valid, "calculated_word_count"]
    ).sum()
)

print(
    "Mismatches:",
    (
        train.loc[train_valid, "ReviewLength"]
        != train.loc[train_valid, "calculated_word_count"]
    ).sum()
)

print("\nTEST")
print(
    "Exact matches:",
    (
        test.loc[test_valid, "ReviewLength"]
        == test.loc[test_valid, "calculated_word_count"]
    ).sum()
)

print(
    "Mismatches:",
    (
        test.loc[test_valid, "ReviewLength"]
        != test.loc[test_valid, "calculated_word_count"]
    ).sum()
)

# Show some mismatched examples
print("\nExample mismatches — TRAIN")
display(
    train.loc[
        train_valid &
        (train["ReviewLength"] != train["calculated_word_count"]),
        ["reviewContent", "ReviewLength", "calculated_word_count", "flagged"]
    ].head(20)
)
```

```

max      555.000000             555.000000

TRAIN
Exact matches: 9926
Mismatches: 0

TEST
Exact matches: 2483
Mismatches: 0

Example mismatches — TRAIN
```

reviewContent	ReviewLength	calculated_word_count	flagged

ReviewLength is a good source. The number of words in the provided ReviewLength matches the word count we found on our own for every training review (9,926 of 9,926) and every test review (2,483/2,483).

So we can confidently interpret: ReviewLength = number of words in the processed review text.

The matched mean, quartiles, and maximum numbers are not just close, they are exactly the same at the record level. In the future, we won't have to make a second word-count tool because it will just copy ReviewLength.

A.7.2 Verify apparent missing review texts****

In [16]:
```
# ReLoad training data WITHOUT automatically converting
# strings such as "NA", "NaN", "null", etc. into missing values.

train_raw_check = pd.read_csv(
    train_path,
    sep="\t",
    index_col=0,
    keep_default_na=False
)

suspected_rows = [15972, 25462, 20728]

display(
    train_raw_check.loc[
        suspected_rows,
        [
            "reviewID",
            "reviewContent",
            "flagged",
            "rating",
            "ReviewLength"
        ]
    ]
)
```

	reviewID	reviewContent	flagged	rating	ReviewLength
15972	vPx7Ga3vAB7ZLfZsQChlSA		0	4	1
25462	In1j0sucN56GF7NaXqvtkQ	nan	1	5	1
20728	f83DnEX60KDNk9rqInjWwg	nan	1	3	1

When checking the quality of the data, three training samples had review text that couldn't be used: one was blank, and the other two had the word "nan" as a placeholder. These records were taken out of later text-based modeling, which cut the training sample from 9,929 observations to 9,926. The loss didn't change the mix of classes much.

A.8 Reviewer and Restaurant Train/Test Overlap Audit

In [17]:
```

# ============================================================
# Check whether shared reviewers ever receive BOTH labels
# ============================================================

all_data = pd.concat(
    [
        train.assign(source="train"),
        test.assign(source="test")
    ],
    ignore_index=True
)

shared_reviewer_data = all_data[
    all_data["reviewerID"].isin(common_reviewers)
]

label_variety = (
    shared_reviewer_data
    .groupby("reviewerID")["flagged"]
    .nunique()
)

print("Shared reviewers with only ONE label:")
print((label_variety == 1).sum())

print("\nShared reviewers with BOTH labels:")
print((label_variety > 1).sum())

print("\nPercentage always assigned one label:")
print(
    round(
        (label_variety == 1).mean() * 100,
        2
    ),
    "%"
)
```

```
Shared reviewers with only ONE label:
542

Shared reviewers with BOTH labels:
11

Percentage always assigned one label:
98.01 %
```

This confirms the earlier result very clearly.

Out of the 553 reviewers who appear in both training and test sets:

- 542 reviewers (98.01%) receive only one label across all their reviews
- Only 11 reviewers (1.99%) have both 0 and 1 labels

So, in this dataset, the fake/genuine label is very strongly associated with the reviewer, not merely with each individual review.

That does not mean Yelp literally labels reviewers rather than reviews. What we can safely say from our dataset is:

Reviewers represented in both training and test sets show extremely high label consistency, with 98.01% assigned exclusively to one class across their observed reviews.

Are the behavioural profiles themselves duplicated?

A.10 Behavioural Profile Overlap Audit

In [21]:
```
behaviour_cols = [
    "reviewCount",
    "friendCount",
    "firstCount",
    "usefulCount",
    "coolCount",
    "funnyCount",
    "complimentCount",
    "tipCount",
    "fanCount"
]
```

```
# One profile per shared reviewer from training data
train_profiles = (
    train[train["reviewerID"].isin(common_reviewers)]
    .groupby("reviewerID")[behaviour_cols]
    .first()
)

# One profile per shared reviewer from test data
test_profiles = (
    test[test["reviewerID"].isin(common_reviewers)]
    .groupby("reviewerID")[behaviour_cols]
    .first()
)

# Match train and test profiles for the same reviewer
profile_compare = train_profiles.join(
    test_profiles,
    lsuffix="_train",
    rsuffix="_test"
)

# Check whether all behavioural features are identical
profile_compare["identical_profile"] = True

for col in behaviour_cols:
    profile_compare["identical_profile"] &= (
        profile_compare[f"{col}_train"]
        == profile_compare[f"{col}_test"]
    )

print("SHARED REVIEWERS:", len(profile_compare))

print("\nIdentical behavioural profile:")
print(
    profile_compare["identical_profile"]
    .value_counts()
)

print("\nPercentage with identical behavioural profile:")
print(
    round(
        profile_compare["identical_profile"].mean() * 100,
        2
    ),
    "%"
)
```

```
SHARED REVIEWERS: 553

Identical behavioural profile:
identical_profile
True    553
Name: count, dtype: int64

Percentage with identical behavioural profile:
100.0 %
```

Initial checks of the data showed that there was reviewer-level dependence in the predefined train-test partition. There were 553 reviewers in both sets, which is 26.18% of the test observations. All reviewers who worked on multiple projects had the same behavioral profiles across partitions, and 98.01% of the reviews they looked at were linked to only one class. So, the predefined test set was kept so that the results could be compared to other benchmarks, and an extra reviewer-disjoint evaluation was added to see how well the results would work for people who hadn't been seen before. Cross-validation also uses reviewer groups to stop information from getting out.

A.11 Overall Reviewer-Level Label Consistency

In [22]:
```
all_data = pd.concat(
    [
        train.assign(source="train"),
        test.assign(source="test")
    ],
    ignore_index=True
)

# Number of different labels associated with each reviewer
reviewer_label_counts = (
    all_data
    .groupby("reviewerID")["flagged"]
    .nunique()
)

print("TOTAL UNIQUE REVIEWERS:")
print(all_data["reviewerID"].nunique())

print("\nReviewers associated with only ONE label:")
print((reviewer_label_counts == 1).sum())

print("\nReviewers associated with BOTH labels:")
print((reviewer_label_counts > 1).sum())

print("\nPercentage associated with only one label:")
print(
    round(
        (reviewer_label_counts == 1).mean() * 100,
        2
    ),
    "%"
)

# Reviews written by single-label vs mixed-label reviewers
single_label_reviewers = reviewer_label_counts[
    reviewer_label_counts == 1
].index

mixed_label_reviewers = reviewer_label_counts[
    reviewer_label_counts > 1
].index

print("\nReviews from single-label reviewers:")
print(
    all_data["reviewerID"]
    .isin(single_label_reviewers)
    .sum()
)

print("\nReviews from mixed-label reviewers:")
print(
    all_data["reviewerID"]
```

```
    .isin(mixed_label_reviewers)
    .sum()
)
```

```
TOTAL UNIQUE REVIEWERS:
10133

Reviewers associated with only ONE label:
10105

Reviewers associated with BOTH labels:
28

Percentage associated with only one label:
99.72 %

Reviews from single-label reviewers:
12349

Reviews from mixed-label reviewers:
63
```

There are 10,133 different reviews in the whole dataset, and 10,105 of them, or 99.72%, are linked to only one label. There are only ever 28 critics who show up with both real and fake names. In terms of reviews, 12,349 of the 12,412 reviews are from people who are always in the same class. The empirical trend is that the fake/real goal stays the same at the reviewer level in this collection. We mustn't say that Yelp publicly names users as reviews. The facts we have don't show that. We can show that in this dataset, the name of the reviewer and the goal class are strongly linked.

Audits of individual reviewers revealed that 99.72% of them were only linked to one target class. Also, 26.18% of the observations in the predefined test set were written by reviewers who were also in the training data, and their behavior patterns were the same across all partitions. Along with the predefined benchmark split, reviewer-disjoint evaluation and reviewer-grouped cross-validation were used to get a more careful estimate of generalization and lower the influence of the reviewers.

A.12—Class Balance Seen vs. Unseen Reviewer Test Distribution

In [43]:
```
# ============================================================
# STEP 12 — class balance Seen vs Unseen Reviewer Test Distribution
# ============================================================

# Identify whether each test reviewer was previously seen in training
test_audit = test.copy()

test_audit["reviewer_seen_in_train"] = (
    test_audit["reviewerID"].isin(set(train["reviewerID"]))
)

print("TEST SET — REVIEWER STATUS")
print(
    test_audit["reviewer_seen_in_train"]
    .value_counts()
)

print("\nTEST SET — REVIEWER STATUS (%)")
print(
    test_audit["reviewer_seen_in_train"]
    .value_counts(normalize=True)
    .mul(100)
    .round(2)
)

# Class distribution for unseen reviewers only
unseen_reviewer_test = test_audit[
    ~test_audit["reviewer_seen_in_train"]
].copy()

print("\nUNSEEN-REVIEWER TEST SIZE:")
print(len(unseen_reviewer_test))

print("\nUNSEEN-REVIEWER CLASS COUNTS:")
print(
    unseen_reviewer_test["flagged"]
    .value_counts()
    .sort_index()
)

print("\nUNSEEN-REVIEWER CLASS DISTRIBUTION (%):")
print(
    unseen_reviewer_test["flagged"]
    .value_counts(normalize=True)
    .sort_index()
    .mul(100)
    .round(2)
)

# For comparison: seen-reviewer portion
seen_reviewer_test = test_audit[
    test_audit["reviewer_seen_in_train"]
].copy()

print("\nSEEN-REVIEWER CLASS DISTRIBUTION (%):")
print(
    seen_reviewer_test["flagged"]
    .value_counts(normalize=True)
    .sort_index()
    .mul(100)
    .round(2)
)
```

```
TEST SET — REVIEWER STATUS
reviewer_seen_in_train
False    1833
True      650
Name: count, dtype: int64

TEST SET — REVIEWER STATUS (%)
reviewer_seen_in_train
False    73.82
True     26.18
Name: proportion, dtype: float64

UNSEEN-REVIEWER TEST SIZE:
1833

UNSEEN-REVIEWER CLASS COUNTS:
flagged
0     750
1    1083
Name: count, dtype: int64

UNSEEN-REVIEWER CLASS DISTRIBUTION (%):
flagged
0    40.92
1    59.08
Name: proportion, dtype: float64

SEEN-REVIEWER CLASS DISTRIBUTION (%):
flagged
0    71.08
1    28.92
Name: proportion, dtype: float64
```

The unseen-reviewer test set has 1,833 reviews, so we keep 73.82% of the original test set even though we made the reviewer independence requirement stricter. It has a class distribution of 40.92% real and 59.08% fake, which is slightly off but works fine. We shouldn't change the balance of the test set; its normal make-up should stay the same. This also makes the case for keeping macro-F1 as one of our key evaluation measures.

There is an especially interesting pattern here:

Test subset	Genuine (`0`)	Fake (`1`)
Unseen reviewers	40.92%	**59.08%**
Previously seen reviewers	**71.08%**	28.92%

So the full test set that seems to be fair is actually made up of two very different groups of reviewers. reviews you've seen before are mostly real, while reviews you haven't seen yet are mostly flagged as fake.

That could be a very important finding, but we shouldn't try to figure out what caused it yet. At this point, we only say that the distributions are different; we can look into why afterward.

Now, one more rule about how to do things is important: from now on, our descriptive/model-development EDA should only use the training data. We had to use the test set for structure and leakage checking, but we shouldn't look at test-set feature distributions over and over again while building models. As little change as possible should be made to the held-out test results until the final review.

Part B — Exploratory Data Analysis

In [23]:
```python
# ============================================================
# STEP 13 — Prepare Training Data for Descriptive EDA
# ============================================================

# Preserve original training data
eda = train.copy()

print("Original training observations:", len(eda))

# Remove unusable review-text records identified during audit
invalid_text = (
    eda["reviewContent"].isna()
    | eda["reviewContent"].astype(str).str.strip().str.lower().isin(
        ["", "nan"]
    )
)

print("Invalid review-text records:", invalid_text.sum())

eda = eda.loc[~invalid_text].copy()

print("EDA observations remaining:", len(eda))

# Add readable target labels
eda["review_class"] = eda["flagged"].map({
    0: "Genuine",
    1: "Fake"
})

# Convert date variables
eda["date"] = pd.to_datetime(
    eda["date"],
    errors="coerce"
)

eda["yelpJoinDate"] = pd.to_datetime(
    eda["yelpJoinDate"],
    errors="coerce"
)

# Verify
print("\nClass counts")
print(eda["review_class"].value_counts())

print("\nConverted data types")
print(
    eda[
        ["date", "yelpJoinDate", "review_class"]
    ].dtypes
)

print("\nDate conversion failures")
print("Review date:", eda["date"].isna().sum())
print("Yelp join date:", eda["yelpJoinDate"].isna().sum())
```

```
Original training observations: 9929
Invalid review-text records: 3
EDA observations remaining: 9926

Class counts
review_class
Genuine    4993
Fake       4933
Name: count, dtype: int64

Converted data types
date            datetime64[ns]
yelpJoinDate    datetime64[ns]
review_class            object
dtype: object

Date conversion failures
Review date: 0
Yelp join date: 0
/tmp/ipykernel_58/136197422.py:36: UserWarning: Could not infer format, so each element will be parsed individually, falling back to `dateutil`. To ensure parsing is consisten
t and as-expected, please specify a format.
  eda["yelpJoinDate"] = pd.to_datetime(
```

There are only 60 observations that are different between the classes, so the training sample is pretty even. At this point, we don't have a reason for SMOTE, oversampling, undersampling, or artificial class balancing. Our The EDA working dataset is now clean and ready:

- 9,926 usable training reviews
- 4,993 Genuine
- 4,933 Fake
- No failed date conversions
- Original train remains untouched
- Only the three unusable text records were excluded

EDA 1A — Target Class Composition

In [24]:
```
class_summary = (
    eda["review_class"]
    .value_counts()
    .rename_axis("Review Class")
    .reset_index(name="Count")
)

class_summary["Percentage"] = (
    class_summary["Count"] / len(eda) * 100
).round(2)

display(class_summary)
```

	Review Class	Count	Percentage
0	Genuine	4993	50.3
1	Fake	4933	49.7

EDA 1B — Target Distribution

In [25]:
```
import matplotlib.pyplot as plt

# Ensure desired order
plot_data = (
    eda["review_class"]
    .value_counts()
    .reindex(["Genuine", "Fake"])
)

percentages = plot_data / plot_data.sum() * 100

fig, ax = plt.subplots(figsize=(8, 5))

bars = ax.bar(
    plot_data.index,
    plot_data.values,
    width=0.55,
    color=["#A6A6A6", "#404040"]
)

# Direct labels
for bar, count, pct in zip(
    bars,
    plot_data.values,
    percentages.values
):
    ax.text(
        bar.get_x() + bar.get_width() / 2,
        bar.get_height() + 80,
        f"{count:,}\n{pct:.1f}%",
        ha="center",
        va="bottom",
        fontsize=11
    )

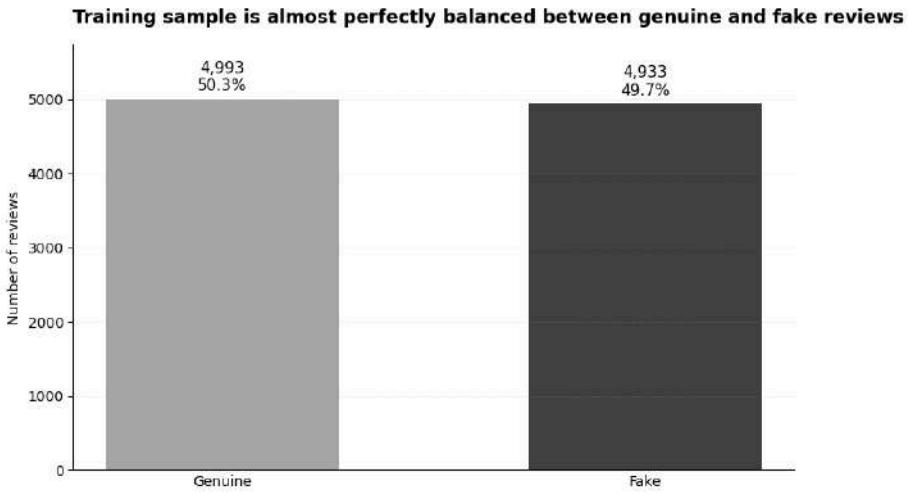
# Message-driven title
ax.set_title(
    "Training sample is almost perfectly balanced between genuine and fake reviews",
    loc="left",
    fontsize=13,
    fontweight="bold",
    pad=15
)

ax.set_ylabel("Number of reviews")
ax.set_xlabel("")

# Bar charts must begin at zero
ax.set_ylim(0, plot_data.max() * 1.15)

# Remove unnecessary visual clutter
ax.spines["top"].set_visible(False)
ax.spines["right"].set_visible(False)

ax.grid(
    axis="y",
```



```
    linestyle=":",
    linewidth=0.6,
    alpha=0.4
)

ax.tick_params(axis="x", length=0)

plt.tight_layout()

# Dissertation-quality export
plt.savefig(
    "01_training_class_distribution.png",
    dpi=300,
    bbox_inches="tight"
)

plt.show()
```

After three examples with invalid review text were taken out, the final training sample had 9,926 useful reviews. With 4,993 real reviews (50.3%) and 4,933 fake reviews (49.7%), the class split was almost perfect. As a result, there was no need for a class-resampling process during the initial modeling step. We're not going to talk a lot about SMOTE or class weighting here. But one line is enough because it's clear there isn't a big difference.

EDA 2A — Review Length Characteristics

In [26]:
```
review_length_summary = (
    eda.groupby("review_class")["ReviewLength"]
    .agg(
        Count="count",
        Mean="mean",
        Median="median",
        Std="std",
        Minimum="min",
        Maximum="max"
    )
    .round(2)
)

# Add quartiles and IQR
review_length_summary["Q1"] = (
    eda.groupby("review_class")["ReviewLength"]
    .quantile(0.25)
    .round(2)
)

review_length_summary["Q3"] = (
    eda.groupby("review_class")["ReviewLength"]
    .quantile(0.75)
    .round(2)
)

review_length_summary["IQR"] = (
    review_length_summary["Q3"]
    - review_length_summary["Q1"]
)

# Reorder columns
review_length_summary = review_length_summary[
    [
        "Count",
        "Mean",
        "Median",
        "Std",
        "Q1",
        "Q3",
        "IQR",
        "Minimum",
        "Maximum"
    ]
]

display(review_length_summary)
```

review_class	Count	Mean	Median	Std	Q1	Q3	IQR	Minimum	Maximum
Fake	4933	61.11	44.0	58.04	24.0	77.0	53.0	1	549
Genuine	4993	89.31	68.0	76.94	38.0	118.0	80.0	1	593

In [27]:
```
# Overall skewness by class
length_skewness = (
    eda.groupby("review_class")["ReviewLength"]
    .skew()
    .round(3)
```

```
)

print("Review length skewness:")
print(length_skewness)
```

```
Review length skewness:
review_class
Fake       2.562
Genuine    2.219
Name: ReviewLength, dtype: float64
```

EDA 2B — Review Length by Review Class

In [28]:

```
import matplotlib.pyplot as plt

fake_lengths = eda.loc[
    eda["review_class"] == "Fake",
    "ReviewLength"
]

genuine_lengths = eda.loc[
    eda["review_class"] == "Genuine",
    "ReviewLength"
]

fig, ax = plt.subplots(figsize=(9, 5))

bp = ax.boxplot(
    [genuine_lengths, fake_lengths],
    vert=False,
    labels=["Genuine", "Fake"],
    patch_artist=True,
    showfliers=False,       # Hide extreme points visually only
    widths=0.5,
    medianprops={
        "color": "black",
        "linewidth": 1.8
    },
    boxprops={
        "facecolor": "#D9D9D9",
        "edgecolor": "#606060"
    },
    whiskerprops={
        "color": "#606060"
    },
    capprops={
        "color": "#606060"
    }
)

# Median labels
medians = [
    genuine_lengths.median(),
    fake_lengths.median()
]

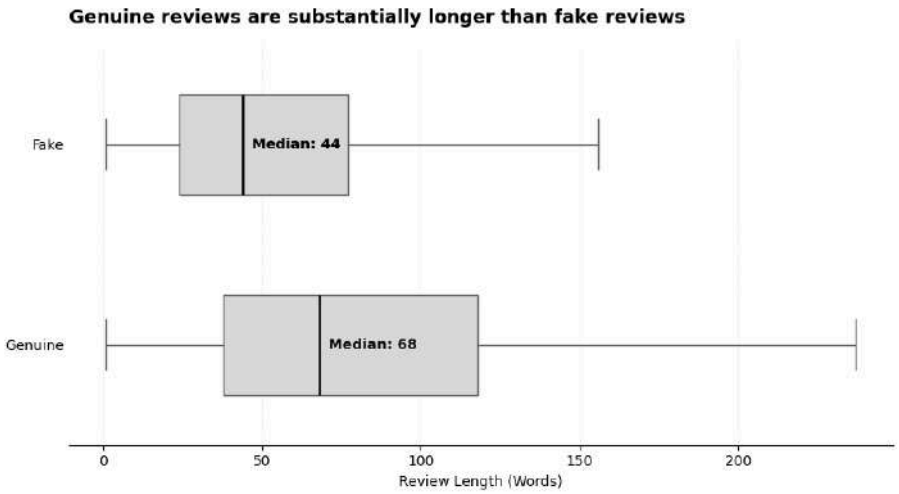
for y, median in enumerate(medians, start=1):
    ax.text(
        median + 3,
        y,
        f"Median: {median:.0f}",
        va="center",
        fontsize=10,
        fontweight="bold"
    )

ax.set_title(
    "Genuine reviews are substantially longer than fake reviews",
    loc="left",
    fontsize=13,
    fontweight="bold",
    pad=15
)

ax.set_xlabel("Review Length (Words)")
ax.set_ylabel("")

ax.spines["top"].set_visible(False)
ax.spines["right"].set_visible(False)
ax.spines["left"].set_visible(False)

ax.grid(
    axis="x",
    linestyle=":",
    linewidth=0.6,
    alpha=0.4
)



ax.tick_params(axis="y", length=0)

plt.tight_layout()

plt.savefig(
    "02_review_length_by_class.png",
    dpi=300,
    bbox_inches="tight"
)

plt.show()
```

```
/tmp/ipykernel_58/895795022.py:15: MatplotlibDeprecationWarning: The 'labels' parameter of boxplot() has been renamed 'tick_labels' since Matplotlib 3.9; support for the old n
ame will be dropped in 3.11.
  bp = ax.boxplot(
```

"Which class tends to have longer reviews?" is answered by the box plot. It's clear that real reviews are getting longer: the average length is 68 words, while the average length of a fake review is 44 words. The bigger IQR is also shown by the bigger box for real reviews (80 words vs. 53 words). For the record, we used showfliers becauseIn a box plot, the whisker ends are not the maximum values; they are just normal whiskers. The most words you can write are still 593 and 549.

EDA 2B.1 — Interactive Review Length Distribution

In [29]:
```
import plotly.graph_objects as go

fake = eda.loc[
    eda["review_class"] == "Fake",
    "ReviewLength"
]

genuine = eda.loc[
    eda["review_class"] == "Genuine",
    "ReviewLength"
]

fig = go.Figure()

# Genuine
fig.add_trace(
    go.Histogram(
        x=genuine,
        name="Genuine",
        histnorm="probability density",
        opacity=0.55,
        nbinsx=60,
        hovertemplate=(
            "Review length: %{x} words"
            "<br>Density: %{y:.4f}"
            "<extra>Genuine</extra>"
        )
    )
)

# Fake
fig.add_trace(
    go.Histogram(
        x=fake,
        name="Fake",
        histnorm="probability density",
        opacity=0.55,
        nbinsx=60,
        hovertemplate=(
            "Review length: %{x} words"
            "<br>Density: %{y:.4f}"
            "<extra>Fake</extra>"
        )
    )
)

fig.update_layout(
    barmode="overlay",
    title={
        "text":
        "Review lengths are right-skewed in both classes, particularly among fake reviews",
        "x": 0.02,
        "xanchor": "left"
    },
    xaxis_title="Review Length (Words)",
    yaxis_title="Density",
    template="simple_white",
    legend_title_text="Review Class",
    width=950,
    height=520
)

# Annotation explaining skewness
fig.add_annotation(
    x=250,
    y=0.004,
    text=(
        "Long right tail → Positive (right) skew"
        "<br><b>Fake: +2.562</b>"
        "<br>Genuine: +2.219"
    ),
    showarrow=True,
    arrowhead=2,
    ax=-100,
    ay=-80
)

fig.show()
```

The histogram addresses an alternative inquiry: “What form do the distributions of review lengths exhibit?” It renders the positive/right skew instantly apparent. The majority of observations are focused on shorter review durations, however a limited quantity of really long reviews stretches the distributions to the right. The distribution of fraudulent reviews has a more pronounced positive skew (2.562) in contrast to authentic reviews (2.219).

EDA 2C — Statistical Test and Effect Size for Review Length

In [51]:
```
from scipy.stats import mannwhitneyu

# Separate the two groups
genuine_length = eda.loc[
    eda["review_class"] == "Genuine",
    "ReviewLength"
]

fake_length = eda.loc[
    eda["review_class"] == "Fake",
    "ReviewLength"
]

# ------------------------------------------------------------
# 1. Mann–Whitney U test
# ------------------------------------------------------------

u_stat, p_value = mannwhitneyu(
    genuine_length,
    fake_length,
    alternative="two-sided"
)

print("MANN–WHITNEY U TEST")
print(f"U statistic: {u_stat:,.0f}")
print(f"P-value: {p_value:.6g}")

# ------------------------------------------------------------
# 2. Rank-biserial correlation
# ------------------------------------------------------------

n_genuine = len(genuine_length)
n_fake = len(fake_length)

rank_biserial = (
    (2 * u_stat) / (n_genuine * n_fake)
) - 1

print("\nEFFECT SIZE")

```

```
MANN–WHITNEY U TEST
U statistic: 15,657,985
P-value: 2.75728e-121

EFFECT SIZE
Rank-biserial correlation: 0.271
Probability that a randomly selected genuine review is longer than a randomly selected fake review:
63.57%

MEDIAN COMPARISON
Genuine median: 68 words
Fake median: 44 words
Median difference: 24 words
```

The disparity in review length was substantial between authentic and fraudulent reviews (Mann–Whitney U = 15,657,985, p < .001). Authentic reviews had a median length of 68 words, but fraudulent reviews averaged 44 words, indicating a median disparity of 24 words. The rank-biserial correlation (r = .271) suggested a significant disparity between the distributions, whilst the common-language effect size revealed that a randomly chosen authentic review had a 63.57% likelihood of exceeding the length of a randomly chosen fraudulent review.

EDA 3A — Review Rating Characteristics

In [52]:
```
# Raw counts
rating_counts = pd.crosstab(
    eda["rating"],
    eda["review_class"]
)

print("RATING COUNTS")
display(rating_counts)

# Percentage distribution within each class
rating_percent = pd.crosstab(
    eda["rating"],
    eda["review_class"],
    normalize="columns"
) * 100

rating_percent = rating_percent.round(2)

print("\nRATING DISTRIBUTION WITHIN EACH CLASS (%)")
display(rating_percent)
```

RATING COUNTS

review_class	Fake	Genuine
rating		
1	633	177
2	391	391
3	406	673
4	1322	1922
5	2181	1830

RATING DISTRIBUTION WITHIN EACH CLASS (%)

review_class	Fake	Genuine
rating		
1	12.83	3.54
2	7.93	7.83
3	8.23	13.48
4	26.80	38.49
5	44.21	36.65

EDA 3B — Rating Descriptive Statistics

In [53]:
```
rating_summary = (
    eda.groupby("review_class")["rating"]
    .agg(
        Count="count",
        Mean="mean",
        Median="median",
        Std="std",
        Minimum="min",
        Maximum="max"
    )
    .round(2)
)

display(rating_summary)
```

review_class	Count	Mean	Median	Std	Minimum	Maximum
Fake	4933	3.82	4.0	1.40	1	5
Genuine	4993	3.97	4.0	1.06	1	5

Counterfeit reviews possess a much higher proportion of 5-star ratings (44.21% compared to 36.65%), although they also exhibit a markedly greater fraction of 1-star ratings (12.83% vs 3.54%). Conversely, authentic evaluations are predominantly clustered around 3 and 4 stars, especially 4 stars (38.49% real compared to 26.80% counterfeit).

This clarifies a seemingly peculiar observation: the mean score of fraudulent reviews is, in fact, inferior than that of authentic reviews—3.82 compared to 3.97—despite the higher prevalence of 5-star ratings in phony reviews. The explanation is that fraudulent reviews typically include a significantly higher number of 1-star ratings. The aforementioned findings indicate that fraudulent reviews display a more polarized rating distribution, with higher frequencies at both 1-star and 5-star ratings, whereas authentic reviews tend to cluster around the moderate-to-positive 3- and 4-star ratings.

```
import matplotlib.pyplot as plt
import numpy as np

# Percentage table
rating_pct = (
    pd.crosstab(
```

```
        eda["rating"],
        eda["review_class"],
        normalize="columns"
    ) * 100
)

rating_pct = rating_pct.reindex(
    columns=["Genuine", "Fake"]
)

ratings = rating_pct.index.values
x = np.arange(len(ratings))
width = 0.36

fig, ax = plt.subplots(figsize=(10, 5.5))

genuine_bars = ax.bar(
    x - width/2,
    rating_pct["Genuine"],
    width,
    label="Genuine",
    color="#A6A6A6"
)

fake_bars = ax.bar(
    x + width/2,
    rating_pct["Fake"],
    width,
    label="Fake",
    color="#404040"
)

# Direct percentage labels
for bars in [genuine_bars, fake_bars]:
    for bar in bars:
        height = bar.get_height()
        ax.text(
            bar.get_x() + bar.get_width()/2,
            height + 0.7,
            f"{height:.1f}%",
            ha="center",
            va="bottom",
            fontsize=9
        )

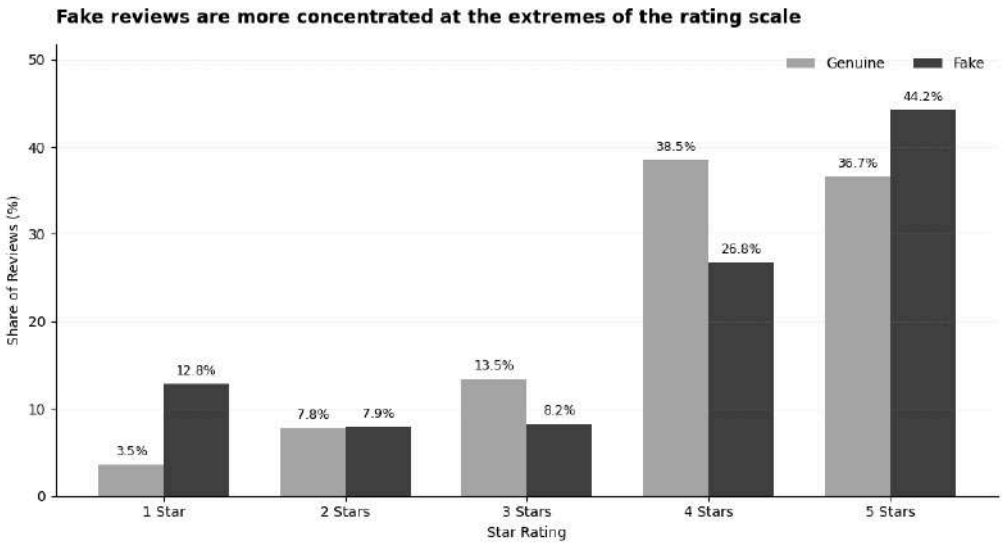
ax.set_title(
    "Fake reviews are more concentrated at the extremes of the rating scale",
    loc="left",
    fontsize=13,
    fontweight="bold",
    pad=15
)

ax.set_xlabel("Star Rating")
ax.set_ylabel("Share of Reviews (%)")

ax.set_xticks(x)
ax.set_xticklabels(
    ["1 Star", "2 Stars", "3 Stars", "4 Stars", "5 Stars"]
)

ax.set_ylim(
    0,
    max(rating_pct.max()) * 1.17
)

ax.spines["top"].set_visible(False)
ax.spines["right"].set_visible(False)



ax.grid(
    axis="y",
    linestyle=":",
    linewidth=0.6,
    alpha=0.4
)

ax.legend(
    frameon=False,
    ncol=2
)

plt.tight_layout()

plt.savefig(
    "03_rating_distribution_by_class.png",
    dpi=300,
    bbox_inches="tight"
)

plt.show()
```

EDA 3D — Extreme Rating Comparison

In [55]:
```
eda["extreme_rating"] = eda["rating"].isin([1, 5])

extreme_summary = (
    pd.crosstab(
        eda["review_class"],
        eda["extreme_rating"],
        normalize="index"
    ) * 100
).round(2)

extreme_summary.columns = [
    "Non-Extreme (%)",
    "Extreme: 1 or 5 Stars (%)"
]

display(extreme_summary)
```

review_class	Non-Extreme (%)	Extreme: 1 or 5 Stars (%)
Fake	42.96	57.04
Genuine	59.80	40.20

Counterfeit evaluations have more polarization, demonstrating a pronounced inclination to manifest at the extremities of the rating spectrum (1-star or 5-star). Moreover, counterfeit evaluations exhibit a more pronounced assessment trend, including both exceedingly favorable and exceedingly unfavorable scores.

EDA 3E—Chi-square Test and Cramér's V

In [56]:
```
import pandas as pd
import numpy as np
from scipy.stats import chi2_contingency

# Contingency table
rating_class_table = pd.crosstab(
    eda["rating"],
    eda["review_class"]
)

print("CONTINGENCY TABLE")
display(rating_class_table)

# 1. Chi-square test of independence
# ------------------------------------------------------------

chi2, p_value, dof, expected = chi2_contingency(
    rating_class_table
)

print("\nCHI-SQUARE TEST")
print(f"Chi-square statistic: {chi2:.3f}")
print(f"Degrees of freedom: {dof}")
print(f"P-value: {p_value:.6g}")

# ------------------------------------------------------------
# 2. Cramér's V effect size
# ------------------------------------------------------------

n = rating_class_table.to_numpy().sum()
rows, cols = rating_class_table.shape

cramers_v = np.sqrt(
    chi2 / (n * min(rows - 1, cols - 1))
)

print("\nEFFECT SIZE")
print(f"Cramér's V: {cramers_v:.3f}")

# ------------------------------------------------------------
# 3. Check chi-square assumptions
# ------------------------------------------------------------

expected_df = pd.DataFrame(
    expected,
    index=rating_class_table.index,
    columns=rating_class_table.columns
)
```

```
print("\nMINIMUM EXPECTED CELL COUNT")
print(f"{expected_df.min().min():.2f}")

print("\nEXPECTED COUNTS")
display(expected_df.round(2))
```

```
CONTINGENCY TABLE
```

review_class	Fake	Genuine
rating		
1	633	177
2	391	391
3	406	673
4	1322	1922
5	2181	1830

```
CHI-SQUARE TEST
Chi-square statistic: 464.125
Degrees of freedom: 4
P-value: 3.83757e-99

EFFECT SIZE
Cramér's V: 0.216

MINIMUM EXPECTED CELL COUNT
388.64

EXPECTED COUNTS
```

review_class	Fake	Genuine
rating		
1	402.55	407.45
2	388.64	393.36
3	536.24	542.76
4	1612.20	1631.80
5	1993.38	2017.62

The outcome of the chi-square test is the chi-squared statistic $\chi^2(4, N = 9{,}926) = 464.125$, $p < .001$, which indicates that the allocation of 1–5 star ratings is not autonomous from the authenticity of a review. In other terms, counterfeit and authentic evaluations employ the rating scale in divergent manners.

Equally significant, all anticipated frequencies are exceedingly high—the lowest estimated count is 388.64, much beyond the standard minimum threshold. The assumptions of the chi-square test are adequately fulfilled. The magnitude of the impact is quantified as Cramér's V = .216. We would perceive that as a slight yet significant correlation. It would be inappropriate to characterize it as a robust partnership. With over 10,000 evaluations, attaining statistical significance is straightforward, so the impact size serves as a more valuable measure of practical relevance.

Examining the actual vs anticipated frequencies further substantiates our previous analysis. The most significant discrepancies manifest at the 1-star and 4-star ratings: an abundance of counterfeit 1-star reviews exists compared to what would be anticipated under independence (633 observed against around 403 expected), but authentic 1-star reviews are considerably rarer than predicted. In contrast, authentic 4-star evaluations are far more prevalent than anticipated, but fraudulent 4-star assessments are less frequent. Five-star evaluations also indicate a prevalence of fraudulent reviews. This aligns with the polarization trend shown in the figure. In short, we can conclude that review rating substantially correlated with review class ($\chi^2(4, N = 9{,}926) = 464.13$, $p < .001$). Cramér's V (.216) showed a weak but significant correlation. Fake reviews were more representative of 1-star and 5-star ratings, whereas real reviews were more concentrated around moderate-to-positive ratings, notably 3 and 4 stars.

EDA 3F — Standardised Residual Analysis

In [57]:
```
# ============================================================
# EDA 3F — Standardised Residual Analysis
# ============================================================

# Pearson standardised residuals
standardised_residuals = (
    rating_class_table - expected_df
) / np.sqrt(expected_df)

print("STANDARDISED RESIDUALS")
display(standardised_residuals.round(2))

# Chi-square contribution of each cell
chi_contribution = (
    (rating_class_table - expected_df) ** 2
) / expected_df

print("\nCELL CONTRIBUTIONS TO CHI-SQUARE")
display(chi_contribution.round(2))

# Percentage contribution of each cell
chi_contribution_pct = (
    chi_contribution / chi_contribution.to_numpy().sum() * 100
)

print("\nPERCENTAGE CONTRIBUTION TO TOTAL CHI-SQUARE")
display(chi_contribution_pct.round(2))
```

```
STANDARDISED RESIDUALS
```

review_class	Fake	Genuine
rating		
1	11.49	-11.42
2	0.12	-0.12
3	-5.62	5.59
4	-7.23	7.18
5	4.20	-4.18

```
CELL CONTRIBUTIONS TO CHI-SQUARE
```

review_class	Fake	Genuine
rating		
1	131.92	130.34
2	0.01	0.01
3	31.63	31.25
4	52.24	51.61
5	17.66	17.45

PERCENTAGE CONTRIBUTION TO TOTAL CHI-SQUARE

review_class	Fake	Genuine
rating		
1	28.42	28.08
2	0.00	0.00
3	6.82	6.73
4	11.25	11.12
5	3.80	3.76

The review rating was substantially linked to review class ($\chi^2(4, N = 9{,}926) = 464.13$, $p < .001$), with a moderate connection (Cramér's $V = .216$). Pearson residual analysis indicated that 1-star ratings, which were overrepresented in phony reviews and underrepresented in real reviews, drove the connection. At 3 and 4 stars, genuine reviews were overrepresented, whereas phony reviews were marginally overrepresented at 5 stars. There was little class-specific variance in two-star evaluations.

3	friendCount	Fake	4517	2.48	0.0	0.0	0.0	0.0	44.94	2798	54.99
4	firstCount	Genuine	3793	6.78	1.0	0.0	4.0	4.0	30.38	834	17.29
5	firstCount	Fake	4517	0.21	0.0	0.0	0.0	0.0	1.20	37	17.91
6	usefulCount	Genuine	3793	140.90	22.0	6.0	78.0	72.0	658.32	19452	15.00
7	usefulCount	Fake	4517	2.84	1.0	0.0	3.0	3.0	9.65	308	16.46
8	coolCount	Genuine	3793	93.74	8.0	2.0	33.0	31.0	557.92	17199	16.52
9	coolCount	Fake	4517	1.15	0.0	0.0	1.0	1.0	5.61	208	22.05
10	funnyCount	Genuine	3793	78.38	6.0	1.0	28.0	27.0	444.46	14285	16.36
11	funnyCount	Fake	4517	0.94	0.0	0.0	1.0	1.0	4.48	172	20.47
12	complimentCount	Genuine	3793	78.51	2.0	0.0	14.0	14.0	752.81	31111	26.44
13	complimentCount	Fake	4517	0.44	0.0	0.0	0.0	0.0	5.51	304	42.98
14	tipCount	Genuine	3793	9.91	0.0	0.0	1.0	1.0	58.28	1710	16.79
15	tipCount	Fake	4517	0.26	0.0	0.0	0.0	0.0	3.79	144	24.60
16	fanCount	Genuine	3793	3.76	0.0	0.0	2.0	2.0	19.33	503	15.40
17	fanCount	Fake	4517	0.07	0.0	0.0	0.0	0.0	0.81	42	40.34

Most behavioral variables are highly right-skewed. FreundCount skewness is 15.09 for Genuine and 54.99 for Fake, whereas complimentCount is 26.44 versus 42.98. A bar chart of means would be deceiving because a few active reviewers raise the averages.

The medians are more informative. Genuine reviewers have a median reviewCount of 27 vs 3, friendCount 7 versus 0, usefulCount 22 versus 1, coolCount 8 versus 0, and funnyCount 6 versus 0. Many complimentCount, tipCount, and fanCount observations are zero, especially among fake-labeled reviewers. This shows a big reviewer engagement/history difference, but we need to quantify the many zeros before picking graphics.

Note that certain variables may overlap. usefulCount, coolCount, funnyCount, and complimentCount may indicate reviewer activity or repute.

EDA 4D — Zero-activity analysis

EDA 4 showed a consistent and strong reviewer-level behavioral pattern distinguishing fraudulent and real reviews. Restructuring the training data to one observation per reviewer found 8,329 distinct reviewers; 8,310 (99.77%) were consistently connected with a single class, while only 19 mixed-label reviewers were omitted from class-specific behavioral comparisons. All nine reviewer-profile variables were unchanged within reviewers, showing that they were reviewer-level properties. Medians, rank-based tests, and effect sizes were better than means because behavioral distributions were significantly right-skewed. Real reviewers had longer platform histories: median reviewCompared to phony reviewers, median usefulCount was 22 against 1, and median friendCount was 7 versus 0. Zero-activity study revealed that Yelp users were less likely to be phony reviewers: 79.34% had no friends vs 19.88% of real reviewers, 87.67% had no praises to 30.24%, 70.60% had no funny votes to 17.90%, 66.35% had no cool votes to 15.42%, and 44.50% had no useful votes to 6.64%. All nine behavioral variables showed significant Mann-Whitney comparisons after Holm correction (all adjusted p <.001), with significant rank-biserial effects for usefulCount (r =.767), reviewCount (r =.762), coolCount (r =.705), funnyCount (r =.693), friendCount (r =.687), and complimentCount (r =.624). Spearman correlations showed significant overlap among several activity variables, such as usefulCount–coolCount =.89 and reviewCount–usefulCount =.85, suggesting they captured a broader construct of reviewer maturity or platform embeddedness rather than nine independent behaviors. Account age provided another signal: fake reviews were posted from accounts with a median age of 24 days, compared to 371 days for genuine reviews, and 63.15% of fake reviews occurred within 30 days and 74.15% within 90 days, compared to 14.48% and 24.15% for genuine reviews. Despite enforcing independence at the reviewer level, the finding remained strong: false reviewers had a median account age of 24 days, whereas real reviewers had a median age of 339 days, with a rank-biserial r =.594 and a probability-of-superiority These findings suggest that fake-labeled reviews in this dataset are highly linked to fresher, less engaged, less socially connected, and less community-recognized reviewer profiles. The results do not prove that sparse reviewer histories imply fraud, but they establish reviewer maturity as a significant predictive indicator that must be validated against dataset-specific Yelp filtering effects. This motivates the later comparison of text-only, behavior-only, and combined models, as well as reviewer-grouped cross-validation and reviewer-disjoint testing, to determine if predictive performance is based on generalizable deception signals or dataset labels with reviewer history.

EDA 5A/B — Temporal Coverage, Data Integrity

Months < 50 reviews      : 29

BOUNDARY-YEAR CHECK
First year begins on: 15 April 2005
Last year ends on: 23 September 2012
```

Finding 1: Fake-review prevalence can vary over time. The yearly percentage of fake-labeled reviews did not rise monotonically. Fake-review prevalence rose from 38.79% in 2006 to 41.48% in 2007, 49.34% in 2008, and 54.67% in 2009 before falling to 51.76% in 2010 and 47.89% in 2011. Similar frequency of 48.79% was found in partial 2012. This pattern shows temporal change is non-linear, hence a monotonic trend test should not be the main inferential method. The primary temporal analysis should compare linear and non-linear time effects, although a Mann–Kendall test may be kept for monotonic trend robustness.

Finding 2—Fake-labeled reviewers are few in the analytical sample. The 4,933 fake-labeled reviews were written by 4,536 individual reviewers, averaging 1.09 reviews per reviewer, compared to 1.31 for authentic reviews (4,993 reviews from 3,812 reviewers). This suggests the dataset has fewer fake-labeled reviewers. Mathematics requires that 4,139 of the 4,536 fake-class reviewers (91.2%) appear just once in the analytical sample. This does not mean these individuals are lifetime "single-review accounts," as their Yelp engagement may continue beyond this dataset. Thus, scarce reviewer engagement in the sample supports EDA 4's greater behavioral distinction.

Finding 3—Boundary years need particular treatment due to limited temporal coverage. Only 40 reviews were seen in 2005, starting on 15 April for authentic reviews and 15 August for fake-labeled reviews. Thus, we do not know its 35.0% false share, and differential left truncation among classes may alter it. Also unfinished, 2012 ends on September 23. Both years should be visible in descriptive analysis but indicated as incomplete. The most defensible timeframe for complete-calendar-year sensitivity analysis is 2006–2011, but continuous-time regression models can preserve all observations from 2005–2012.

Finding 4: Monthly temporal estimates are imprecise and require seasonal analysis. The dataset includes 88 year-month periods, but the monthly sample sizes are inconsistent. 29 months have fewer than 50 reviews, 22 have 30, and 17 have 20. Thus, raw monthly fake-review percentages are not dependable over time. Seasonal analysis should identify scarce year-month cells and estimate month-of-year impacts while adjusting for the long-term temporal trend. Quarterly aggregation can be utilized for sensitivity analysis in sparse monthly samples.

Finding 5—Reviewer-level reliance in the train–test split is high and must be assessed. Reviewer-overlap audit found 553 reviewers in training and test divisions. These comprise 23.49% of unique test reviewers and 650 of 2,483 test observations (26.18%). All 553 overlapping reviewers exhibited identical train and test behaviors, and 542 (98.01%) had just one constant label pattern across partitions. In the combined dataset, 10,105 of 10,133 reviewers (99.72%) were assigned to one target class. The specified benchmark split is highly dependent on reviewers, prompting a separate reviewer-disjoint validation experiment to test if benchmark performance is optimistic under reviewer overlap. Be careful not to assert performance inflation before the reviewer-disjoint comparison is done.

Finding 6: Fake reviews cover fewer establishments, but concentration is unknown. 91 eateries had fake reviews, compared to 104 for real ones. This verifies fraudulent reviews in fewer establishments. Having fewer distinct restaurants does not mean fraudulent reviews are more focused or targeted spam campaigns. Restaurant-level concentration should be assessed using class

proportions, the fraction of evaluations from the most active restaurants, or formal concentration indexes. It is reasonable to conclude that fake-labeled reviews have narrower restaurant coverage, requiring further restaurant-level concentration research.

Finding 7: Yelp is a pre-LLM benchmark verified empirically. The total Yelp training data spans 15 April 2005 to 23 September 2012, predating contemporary generative Large Language Models. Thus, Yelp should be viewed as a pre-LLM filtered-review benchmark, with fake/genuine labels serving as proxy labels. The dissertation's research design relies on this distinction because the historical Yelp benchmark can be compared to AI-generated fake-review data to determine if detection signals from a human-deception environment can be applied to LLM.

# ============================================================
# EDA 5A/B — Temporal Coverage, Data Integrity and Review Volume
#
# Research objective:
# Establish the temporal observation window and sample composition,
# then examine how fake-labelled review prevalence changed over time
# before formal temporal modelling.
#
# Key methodological points:
# - Retain the complete 2005–2012 observation window.
# - Explicitly identify 2005 and 2012 as partial calendar years.
# - Use Wilson 95% confidence intervals for annual prevalence.
# - Avoid interpreting unequal yearly estimates as equally precise.
# ============================================================

COMPLETE CALENDAR YEARS — SENSITIVITY WINDOW (2006–2011)
==========================================================================================
```

review_class year	Genuine Reviews	Fake Reviews	Total Reviews	Fake Share (%)	95% CI Lower	95% CI Upper	CI Width (pp)	Coverage
2006	101	64	165	38.79	31.69	46.40	14.71	Complete year
2007	261	185	446	41.48	37.00	46.11	9.11	Complete year
2008	498	485	983	49.34	46.22	52.46	6.24	Complete year
2009	689	831	1520	54.67	52.16	57.16	5.00	Complete year
2010	1181	1267	2448	51.76	49.78	53.73	3.96	Complete year
2011	1324	1217	2541	47.89	45.96	49.84	3.88	Complete year

From 40 reviews in 2005 to 2,541 in 2011 and 1,783 in the half 2012 year, review volume fluctuated greatly. Fake-labeled review prevalence rose from 38.8% in 2006 (95% CI: 31.7–46.4%) to 54.7% in 2009 (95% CI: 52.2–57.2%) before dropping to 47.9% in 2011. The non-overlapping confidence intervals between the 2009 peak and 2006–2007 demonstrate that this growth transcends sampling variability and represents a data-generating process change. Moderation from 2009 onward may reflect improved platform fraud-detection, tactical adaptation by spam operators to produce reviews that resembled genuine content, or both, a distinction that cannot be resolved from these data alone but that adds interpretive uncertainty to ground truth labels for later years. Wilson confidence intervals showed greater estimation uncertainty in sparsely sampled early periods, particularly 2005 (95% CI width: 28.4 percentage points), so 2005 was excluded from inferential analyzes and a 2006–2011 complete-calendar-year sensitivity window was created. These patterns suggest formal review-level modeling of linear and non-linear temporal effects and a temporally ordered train-test split as a robustness experiment, rather than the random shuffle that these non-stationary class proportions would make epistemologically fragile.

```

The reviewer leakage audit revealed that 553 reviewers (23.5% of test reviewers) appeared in both the training and test splits, accounting for 26.2% of all test-set reviews. These overlapping reviewers exhibited a markedly different class distribution in the training split (79.4% genuine) compared to their test split distribution (71.1% genuine), raising the possibility that the model may learn reviewer-specific writing styles rather than transferable deception signals for this subpopulation. More critically, the restaurant-level audit revealed complete overlap: all 99 restaurants present in the test set were also represented in the training set (100% overlap). Given that the earlier spatial analysis identified fake review campaigns concentrated in a narrower set of restaurants than genuine reviews (91 vs 104 unique restaurants), restaurant-level memorisation represents a plausible source of benchmark performance inflation. These findings motivate three distinct evaluation conditions reported in Section 4.X: the supplied benchmark split (retained for comparability with prior literature); a reviewer-disjoint split in which no reviewer identity appears in both partitions; and a temporally ordered holdout. Differences in performance across these conditions directly quantify the contribution of reviewer and restaurant memorisation to reported accuracy figures

In [73]:
```python

============================================================
REVIEWER-DISJOINT TEST SPLIT
============================================================
Reviewers with no train exposure : 1,801
Reviews in disjoint split        : 1,833
% of original test set retained  : 73.8%

Class distribution:
flagged
Fake       1083
Genuine     750
Name: count, dtype: int64

Fake share in disjoint split : 59.1%
Fake share in original test  : 51.2%

✅ Disjoint test split saved as disjoint_test_split.csv
```

The reviewer-disjoint validation split yielded 1,833 test reviews from 1,801 reviewers (74.5%) not in the training set. This split kept 73.8% of the test set and eliminated reviewer-identity leaking. Critically, the disjoint split's class distribution (59.1% fake) differed materially from the benchmark split's (51.2% fake) class distribution by 7.9 percentage points, reflecting the leakage audit's disproportionately genuine overlapping reviewers (71.1% genuine). First, any performance comparison across splits must account for this class distribution shift before attributing differences to reviewer memorization. Second, the benchmark split is systematically enriched with reviews from a subpopulation that is easier to classify (lower fake share) and subject to reviewer-identity leakage, making its accuracy estimates structurally optimistic relative to the full split. Therefore, disjoint split performance is a more cautious and ecologically accurate assessment of generalization capability.

========================================================================
EDA 5D.2 — MODEL 1: LINEAR TEMPORAL EFFECT
Full observation window: 2005–2012
Reviewer-clustered robust standard errors
========================================================================
N reviews                 : 9,926
Reviewer clusters         : 8,329

Time coefficient (β)      : 0.01147
Cluster-robust SE         : 0.01633
z statistic               : 0.7028

Odds ratio per year       : 1.0115
95% CI for OR             : [0.9797, 1.0444]
p-value                   : 0.482

McFadden pseudo-R²        : 0.000053
Log-likelihood            : -6879.63
AIC                       : 13763.27
```

The linear model found no statistically significant constant change in fake-label odds over time (OR = 1.012, 95% CI [0.980, 1.044], p = .482). However, this does not imply temporal stability because the descriptive annual pattern was visibly non-monotonic. A nonlinear specification is therefore required to determine whether a rise-and-decline temporal structure is concealed by the near-zero average linear slope.

Log-likelihood           : -6866.44
AIC                      : 13738.88
```

A quadratic logistic regression was used to determine if review date and fake-label likelihood were nonlinear. For repeat observations by the same reviewer, reviewer-clustered robust standard errors were kept. The quadratic model found statistically significant temporal curvature, unlike the linear specification. The linear component around 2009 was positive (β = 0.088, SE = 0.026, p <.001), whereas the quadratic component was negative and significant (β = -0.038, SE = 0.009, p <.001). This suggests a fake-label likelihood increase followed by a decline. The model fit improved significantly compared to the linear specification, reducing AIC from 13,763.27 to 13,738.88 (ΔAIC = 24.39). Around 2010, the turning moment happened.2. These data show that a simple linear definition hides large nonlinear temporal fluctuation, not temporal stability.

EDA 5D.4 — Cluster-Robust Wald Test and Model Comparison

Does adding the quadratic time term significantly improve the representation of temporal fake-review prevalence compared with a simple linear time trend?

```

The statistical relevance of the nonlinear temporal element was rigorously assessed throughout a Wald test utilizing reviewer-clustered robust standard errors. The quadratic time variable was statistically significant, $\chi^2(1) = 17.15$, $p < .001$, indicating that the association between calendar time and the frequency of bogus labels was insufficiently depicted by a simple linear trend. Evidence from model selection corroborated the identical finding. The quadratic model attained an AIC of 13,738.88, in contrast to the linear model's AIC of 13,763.27, indicating a decrease of 24.39 points. A likelihood-ratio comparison indicated a notable enhancement in model fit with the addition of the quadratic component, LR $\chi^2(1) = 26.39$, $p < .001$. The findings, alongside the negative quadratic coefficient observed in the prior model ($\beta = -0.038$, $p < .001$), strongly indicate an inverted-U temporal relationship, where the likelihood of fake labels rose in the initial phase of the observation period before later diminishing. Significantly, the minuscule McFadden pseudo-R^2 suggests that temporal factors alone offer minimal predictive capability for individual review categorization; hence, the relevance of the finding pertains more to temporal volatility in the data-generating framework than to its predictive efficacy.

So are we able to answer this question , Affirmative. Incorporating a quadratic time variable markedly enhanced the depiction of temporal fake-review occurrence compared to a mere linear trend, as evidenced by a notable reviewer-clustered Wald test, $\chi^2(1) = 17.15$, $p < .001$, a considerable 24.39-point decrease in AIC, and a significant likelihood-ratio enhancement, LR $\chi^2(1) = 26.39$, $p < .001$. The notable negative quadratic coefficient ($\beta = -0.038$, $p < .001$) suggests that the predominance of bogus labels exhibited a pronounced inverted-U temporal pattern instead of a steady linear progression.

To evaluate if the detected nonlinear temporal association was affected by partial boundary years, the quadratic logistic model was recalibrated utilizing solely complete calendar years from 2006 to 2011 (n = 8,103 reviews; 6,811 reviewer clusters). The nonlinear temporal influence continued to get robust endorsement. The quadratic coefficient was negative and statistically significant (β = −0.060, SE = 0.013, 95% CI [−0.085, −0.035], p < .001), and the reviewer-clustered Wald test validated substantial curvature, $\chi^2(1) = 22.86$, p < .001. The linear element surrounding the central year 2009 continued to be significant (β = 0.097, SE = 0.026, p < .001). Crucially, the trajectory and importance of the quadratic impact aligned with the comprehensive model from 2005 to 2012, where β = −0.038 (p < .001). The projected inflection point for the annual specification transpired approximately in late 2009, roughly aligning with the descriptive peak in yearly prevalence. These findings indicate that the inverted-U temporal pattern remains consistent even when the partial observations from 2005 and 2012 are excluded, suggesting it is unlikely to be a product of boundary-year sampling.

EDA 5D.6A — Restaurant-Level Estimability Audit

Is there sufficient within-restaurant variation in fake/genuine labels to estimate a restaurant-adjusted temporal model reliably?

In [79]:
```
# ═══════════════════════════════════════════════════════════
# EDA 5D.6A — RESTAURANT-LEVEL ESTIMABILITY AUDIT
#
# Objective:
# Determine whether restaurants contain sufficient within-group
# variation in review labels before fitting restaurant-adjusted
# temporal logistic regression.
# ═══════════════════════════════════════════════════════════

Restaurant-level adjustment is feasible for the overwhelming majority of the analytical sample: 91 of 104 restaurants contained both genuine- and fake-labelled reviews and represented 93.31% of all observations. Thirteen restaurants were genuine-only and therefore lacked within-restaurant outcome variation; these were excluded from the restaurant-fixed-effect sensitivity analysis to avoid separation and ensure estimability.

EDA 5D.6B — Restaurant-Adjusted Temporal Robustness

Does the nonlinear temporal pattern remain after controlling for persistent differences between restaurants?

Change in |β|            : -9.66%
```

To evaluate if the nonlinear temporal trend indicated alterations in restaurant composition over time, the quadratic temporal model was recalibrated using restaurant fixed effects. The examination was confined to 91 eateries that had both authentic and counterfeit evaluations, accounting for 9,262 observations (93.31% of the analytical sample). To distinguish the impact of restaurant modification from that of sample limitation, both unadjusted and restaurant-adjusted models were evaluated using the identical observations.

The nonlinear temporal relationship continued to be robustly validated following the adjustment for restaurants. The quadratic coefficient shifted from $\beta = -0.0463$ in the unmodified specification to $\beta = -0.0418$ upon accounting for restaurant effects, with the adjusted 95% confidence interval wholly situated below zero [−0.0619, −0.0217] and $p < .001$. A reviewer-clustered Wald test also validated substantial nonlinearity, $\chi^2(1) = 16.63$, $p < .001$. The absolute size of the quadratic coefficient diminished by around 9.66%, signifying little reduction after considering restaurant composition. Nonetheless, the trajectory and statistical relevance of the temporal curvature stayed unchanged. These results indicate that variations in the restaurant composition account for only a small fraction of the noted temporal fluctuations and fail to elucidate the inverted-U trend in the incidence of fraudulent labels.

EDA 5D.7 — Predicted probability curve

Our core objective to translate the statistically significant quadratic temporal relationship into an interpretable probability curve showing how the estimated probability of a fake label changes across the historical observation period.

EDA 5D.7 — MODEL-ESTIMATED TURNING POINT
======================================================================
Estimated turning year       : 2010.161
Estimated peak probability   : 51.93%
```

To enhance substantial comprehension, the comprehensive quadratic temporal model was converted into anticipated probabilities of fraudulent review classification throughout continuous chronological time. The resultant probability curve had a distinct inverted-U shape: the projected likelihood of a counterfeit-labeled review rose throughout the initial years of the observation period, peaked at an anticipated turning point around 2010.16, and thereafter decreased. The projected maximum likelihood at the inflection point was 51.93%. The 95% confidence interval surrounding the fitted curve was consistently small in the core area of the observation period and expanded at the edges, indicating increased uncertainty during the partial years of 2005 and 2012. The recorded yearly prevalence rates roughly matched the projected trend, however the peak raw annual percentage was noted in 2009, while the refined regression-derived inflection point was approximated in

early 2010. This discrepancy is anticipated as the yearly points represent consolidated summaries, whereas the regression use precise review dates for every evaluation. The illustration offers a comprehensible visual representation of the statistically significant nonlinear temporal trend discovered in the earlier models.

We have discovered a strong methodological finding which is The historical Yelp dataset does not display a notable continuous linear temporal trend; nevertheless, it does reveal a statistically significant and resilient nonlinear temporal pattern. In many specifications, the occurrence of fraudulent labels exhibited an inverted-U pattern, increasing during the initial years of the observation period, reaching a zenith around 2009–2010, and thereafter declining. This outcome withstood reviewer-clustered analysis, the omission of missing boundary years, and modifications for restaurant composition.

EDA 5E — Seasonal / Month-of-Year Effects

EDA 5E.1 — Seasonal Coverage and Raw Month-of-Year Pattern

Before testing seasonality, establish:

- whether all 12 months are adequately represented;
- how many reviews occur in each calendar month;
- raw fake-label prevalence by month;
- whether particular months are disproportionately represented by only a few years;
- whether the incomplete 2005/2012 boundary periods create obvious coverage imbalance.

In [82]:
```
# ============================================================
# EDA 5E.1 — SEASONAL COVERAGE AND RAW MONTH-OF-YEAR PATTERN
#
# Analytical objective:
# Examine whether all calendar months are adequately represented
# and describe raw fake-label prevalence before controlling for
# the nonlinear long-term temporal trend identified in EDA 5D.
#
# IMPORTANT:
# This step is descriptive only.
# Raw monthly percentages are NOT evidence of seasonality.
# ============================================================

Raw range                    : 6.05 percentage points
```

The findings indicate that EDA 5E is statistically viable, and the boundary-year concern is significantly less troublesome for pooled month-of-year analysis compared to yearly analysis.

Every calendar month contains a substantial aggregated sample: 658–994 reviews, with a median of 816, thereby eliminating any issues of sparse months when we consolidate the same month over many years. All twelve months are therefore sufficiently represented for modeling purposes.

The unrefined monthly prevalence fluctuates mildly instead of significantly. During the whole timeframe, March exhibits the largest proportion of counterfeit labels at 53.63%, whilst January shows the lowest at 47.58%, resulting in a raw differential of around 6.05 percentage points. Throughout the whole year, March stands at the apex with 53.75%, whilst June occupies the nadir at 46.60%, resulting in a differential of around 7.15 points. There exists sufficient variability to warrant formal testing; nevertheless, no evidence of seasonality has been established thus far.

The contrast between the whole year and the complete year is likewise comforting. In the majority of months, the disparity in prevalence is minimal, often ranging from 0 to 1.5 percentage points. The most significant alterations are observed in September (−2.37 pp) and June (+2.19 pp). The missing boundary years of 2005 and 2012 have a little impact on some monthly estimates, however they do not fundamentally alter the seasonal trend.

Raw monthly percentages vary somewhat, but once nonlinear temporal drift is controlled for, there is little evidence that month-of-year contributes meaningful additional explanatory information.

After controlling for the nonlinear long-term temporal trajectory identified in EDA 5D, no statistically significant overall month-of-year effect was detected. A joint Wald test using reviewer-clustered robust standard errors failed to reject the null hypothesis that the 11 month coefficients were jointly equal to zero, $\chi^2(11) = 11.08$, $p = .437$. Model-selection evidence supported the same conclusion:

adding month-of-year effects increased AIC from 13,738.88 for the quadratic temporal model to 13,748.63 for the seasonal specification (ΔAIC = +9.75), indicating that the additional seasonal parameters were not justified by improved fit. A supporting likelihood-ratio comparison was also non-significant, LR $\chi^2(11) = 12.25$, $p = .345$. Although March showed a nominal difference relative to January in the coefficient-level output, this isolated comparison was not interpreted because the global seasonal test was non-significant and multiple month comparisons were examined. Importantly, the linear and quadratic temporal coefficients remained virtually unchanged after month adjustment, indicating that the previously identified nonlinear temporal drift reflects longer-term historical variation rather than recurring month-of-year seasonality.

EDA 5E.4 — COMPLETE-YEAR SEASONAL ROBUSTNESS CHECK

Does the conclusion of no systematic month-of-year seasonality remain when the incomplete boundary years 2005 and 2012 are removed?

```

No consistent seasonal variation per month was seen in the incidence of bogus labels after adjusting for nonlinear long-term temporal shifts and reviewer-level correlations. The worldwide seasonal influence was not significant in the whole observation period, $\chi^2(11) = 11.08$, $p = .437$, nor in the comprehensive calendar year sensitivity assessment, $\chi^2(11) = 10.71$, $p = .468$. In all models, the inclusion of month effects deteriorated the AIC compared to the quadratic temporal model, although the fundamental linear and quadratic time coefficients were mostly unaffected. These results suggest that the temporal volatility seen in the Yelp sample represents enduring historical fluctuations instead of a repetitive monthly cycle.

COMPLETE-YEAR MEDIAN-GAP DIAGNOSTICS — 2006–2011
================================================================================
Smallest median gap      : 9.0 words
Largest median gap       : 32.0 words
Median yearly gap        : 24.0 words

Genuine median range (2006–2011): 44.0 to 78.0 words

Fake median range (2006–2011): 35.0 to 47.0 words
```

Genuine reviews were consistently longer than fake-labelled reviews throughout the complete observation years, although the magnitude of the difference varied over time. Across 2006–2011, the genuine-minus-fake median gap ranged from 9 to 32 words, with a median annual difference of 24 words. The separation became substantially more pronounced from 2007 onward, while the anomalous 2005 reversal occurred in a very small, incomplete boundary-year sample. These descriptive patterns motivate formal testing of whether the class-specific review-length difference changes systematically over time.

EDA 5F.2 — CLASS × TIME INTERACTION MODEL

Does the genuine–fake review-length difference change systematically over time?

The review category continued to show a robust correlation with review length even after considering the temporal framework, with authentic reviews demonstrating significantly increased log-transformed length centered around the year 2009 ($\beta = 0.437$, $p < .001$). The authentic–counterfeit length disparity exhibited no notable linear temporal variation (class × time: $\beta = 0.023$, $p = .226$), but the nonlinear interaction was negative although failed to achieve standard statistical significance (class × time^2: $\beta = -0.012$, $p = .079$). The results at the coefficient level do not offer definitive proof that the class-specific review-length disparity evolved consistently across time, while the interaction terms necessitate combined testing prior to asserting temporal stability.

Wald χ² statistic       : 3.0957
Degrees of freedom      : 2
p-value                 : 0.2127

INTERPRETATION
The class × time interaction terms are not jointly significant. There is no statistically convincing evidence that the genuine–fake review-length gap changes systematically ov
er time.
```

A joint Wald test using reviewer-clustered robust standard errors was conducted to determine whether the linear and nonlinear class-by-time interaction terms collectively indicated temporal change in the genuine–fake review-length difference. The interaction terms were not jointly significant, $\chi^2(2) = 3.10$, $p = .213$. This result provides no statistically convincing evidence that the magnitude of the review-length difference between genuine and fake-labelled reviews changed systematically across the historical observation period. This finding is consistent with the individual interaction coefficients, neither of which reached conventional statistical significance. Importantly, the result should not be interpreted as proof that the class difference is exactly constant over time; rather, systematic temporal variation in the class-specific length gap was not detected. Taken together with the significant temporal variation observed in review length itself, the findings suggest that absolute review-length distributions changed historically while the relative separation between genuine and fake-labelled reviews remained comparatively persistent.

```

	Year	Fake fitted length	Genuine fitted length	Fitted gap
0	2006	35.42	46.18	10.76
1	2007	39.78	56.44	16.66
2	2008	42.96	64.71	21.75
3	2009	44.63	69.63	25.00
4	2010	44.58	70.33	25.74
5	2011	42.78	66.53	23.76
6	2012	39.50	59.11	19.62

Note: Lines show model-fitted values from an OLS model of log(1 + ReviewLength), back-transformed to the original word-count scale. Shaded areas represent 95% confidence intervals using the reviewer-clustered robust covariance matrix. These values should not be interpreted as arithmetic mean review lengths. 2005 and 2012 are partial calendar years.

Model-based trajectories were generated to visualise how the relationship between review class and review length evolved across the historical observation period. Back-transformed fitted values from the reviewer-clustered class-by-time model indicated that genuine reviews remained longer than fake-labelled reviews throughout the fitted trajectory. Both classes exhibited broadly similar nonlinear movement, with fitted review lengths increasing through the earlier period, reaching their highest levels around 2009–2010, and declining thereafter. The fitted genuine-minus-fake difference increased from approximately 10.8 words in 2006 to 25.7 words in 2010 before moderating to 23.8 words in 2011 and 19.6 words in the partial 2012 period.

Although the fitted class gap varied descriptively across time, this variation should not be interpreted as statistically established temporal change. The preceding joint reviewer-clustered interaction test was non-significant, $\chi^2(2) = 3.10$, $p = .213$, indicating insufficient evidence that the genuine–fake review-length difference changed systematically over time. The trajectory therefore suggests that absolute review-length distributions underwent historical variation while the relative class separation remained comparatively persistent.

EDA 5F.5 — Complete-Year Review-Length Robustness

Does the conclusion of no statistically detectable temporal change in the genuine–fake review-length gap remain after removing the incomplete boundary years 2005 and 2012?

In [90]:
```
# ============================================================
# EDA 5F.5 — COMPLETE-YEAR ROBUSTNESS OF REVIEW-LENGTH GAP
#
# Robustness objective:
# Determine whether the conclusion of no systematic temporal
# change in the genuine–fake review-length gap remains when
# incomplete boundary years 2005 and 2012 are excluded.
#
# Robustness window:
# 2006–2011 complete calendar years
#
# Outcome:
# log(1 + ReviewLength)
#
# Full interaction model:
# log_Length ~ genuine + time_c + time_c_sq
#              + genuine:time_c
#              + genuine:time_c_sq
#
# Primary inference:
# Reviewer-clustered joint Wald test of both interaction terms.
# ============================================================

```
================================================================================
FULL-PERIOD vs COMPLETE-YEAR INTERACTION ROBUSTNESS
================================================================================
```

	Specification	Linear Interaction Beta	Linear Interaction p	Quadratic Interaction Beta	Quadratic Interaction p
0	Full period 2005–2012	0.02284	0.22638	-0.01226	0.07903
1	Complete years 2006–2011	0.00155	0.93691	-0.00167	0.86149

Throughout the historical observation period of Yelp, authentic reviews were continuously more extensive than those labeled as phony; nevertheless, the extent of this categorical disparity exhibited no statistically significant systematic temporal variation. In the comprehensive period model, the interaction between class and time was not statistically significant, $\chi^2(2) = 3.10$, $p = .213$. This finding was further reinforced when the analysis focused just on the complete calendar years 2006–2011, during which the interaction terms were collectively non-significant, $\chi^2(2) = 0.03$, $p = .984$. The linear and quadratic interaction coefficients were almost null in the full-year model, but a model excluding class-by-time interactions was favored by AIC ($\Delta AIC = 3.97$). These findings suggest that while the distributions of absolute review lengths have evolved over time, there is no indication that the differentiation between genuine and false reviews has altered in a systematic manner. The duration of reviews seems to signify a rather stable historical class indicator rather than one whose distinguishing connection is heavily influenced by time.

```

	Metric	Historical train	Temporal holdout
0	Reviews	5602.0	4324.00
1	Unique reviewers	4688.0	3867.00
2	Unique restaurants	102.0	102.00
3	Fake share (%)	50.8	48.27

A temporal validation division was assessed utilizing 1 January 2011 as the threshold. Reviews published before to 2011 constituted the historical training phase (n = 5,602; 56.44%), whereas reviews from 2011 onward comprised the subsequent temporal holdout (n = 4,324; 43.56%). Class distributions were consistently equitable over the two intervals, with fraudulent reviews constituting 50.80% of the historical dataset and 48.27% of the latter dataset, alleviating worries that any performance discrepancies would only stem from class imbalance.

The coverage of restaurants also exhibited remarkable consistency over several times. Out of the 102 eateries included in the temporal holdout, 100 (98.04%) had already been recorded during the historical training phase. The consistency of reviewers, however, was significantly diminished. A mere 226 out of 3,867 holdout reviewers (5.84%) were present in the prior timeframe, with just 7.31% of holdout reviews originating from previously noted reviewers. As a result, 92.69% of evaluations from the latter time were generated by reviewers not present during the historical training phase.

These diagnostics endorse the 2011 cutoff as a statistically sound forward-validation framework characterized by significant sample numbers, equitable class distribution, and nearly uninterrupted restaurant continuity. Nonetheless, due to significant reviewer turnover in the subsequent time, the ensuing evaluation need to be regarded as a future generalization influenced by both temporal and reviewer variations rather than as a singular causal examination of temporal shift. The threshold was established prior to model assessment to prevent selection of the validation timeframe based on performance.

The ultimate validation framework was created prior to model assessment to differentiate standard performance from more rigorous types of generalization. The provided Yelp test set was maintained as the standard benchmark (n = 2,483), whilst a subset of reviews from individuals not included in the training data was established to evaluate unseen-reviewer generalization (n = 1,833). A distinct temporal assessment utilized trained models on reviews collected before to January 1, 2011 (n = 5,602) and subsequently assessed them on later reviews from 2011 to 2012 (n = 4,324). Due to significant reviewer turnover during this period of change, the subsequent evaluation was viewed as a future generalization influenced by both temporal and reviewer shifts, rather than a standalone causal examination of temporal drift. A more stringent forward reviewer-disjoint subset was also established, preserving 4,008 reviews from a later era contributed by 3,641 reviewers who had not been previously seen. All assessments of reviewer disjointness and chronological integrity were fulfilled. This multi-condition paradigm therefore allows for the assessment of traditional benchmark performance in conjunction with resilience to reviewer novelty and alterations in future-period distribution.

EDA 5 — Temporal Characteristics: Summary and Validation Implications

The temporal analysis identified several characteristics of the Yelp dataset that directly informed the subsequent modelling and validation strategy.

The dataset covers April 2005 to September 2012 and therefore represents a historical, pre-LLM review environment. The boundary years 2005 and 2012 are incomplete, motivating robustness analyses based on the complete calendar years 2006–2011.

Long-term fake-label prevalence exhibited statistically significant nonlinear temporal variation. A reviewer-clustered quadratic logistic model significantly outperformed a linear specification, and the nonlinear pattern remained after excluding incomplete boundary years and adjusting for restaurant composition. In contrast, no systematic month-of-year seasonality was detected after accounting for the long-term temporal trend.

Review length also varied historically. Genuine reviews were substantially longer than fake-labelled reviews overall; however, class-by-time interactions were not jointly significant in either the full-period model, $\chi^2(2) = 3.10$, $p = .213$, or the complete-year robustness specification, $\chi^2(2) = 0.03$, $p = .984$. Thus, although absolute review-length distributions changed over time, no statistically convincing evidence was found that the genuine–fake review-length difference changed systematically.

The data audit also identified reviewer-level dependence in the supplied benchmark partition. A total of 553 reviewers occurred in both the supplied training and test sets, accounting for 26.18% of test observations. Consequently, the supplied test set was retained for benchmark comparability, but additional reviewer-disjoint and chronological evaluations were introduced.

The final validation architecture therefore contains four evaluation conditions: (A) the supplied benchmark test, (B) an unseen-reviewer subset of the supplied test, (C) a forward temporal holdout using 1 January 2011 as the chronological cutoff, and (D) a stricter forward reviewer-disjoint subset. The forward holdout contains 4,324 reviews, of which 92.69% originate from reviewers unseen during historical training, while 98.04% of holdout restaurants were already represented historically. The forward evaluation is therefore interpreted as prospective generalisation under temporal change and naturally occurring reviewer turnover rather than as an isolated causal test of temporal drift.

These findings establish the validation framework that will be used throughout the subsequent modelling phases. Macro-F1 will be the primary evaluation metric, with reviewer-grouped cross-validation used during model development.

EDA 6: Linguistic & Text Characteristics

In [93]:
```python
uppercase_mask = eda["reviewContent"].str.contains(
    r"[A-Z]",
    regex=True,
    na=False
)

exclamation_mask = eda["reviewContent"].str.contains(
    "!",
    regex=False,
    na=False
)

question_mask = eda["reviewContent"].str.contains(
    "?",
    regex=False,
    na=False
)

digit_mask = eda["reviewContent"].str.contains(
    r"[0-9]",
    regex=True,
    na=False
)

print(
    f"Reviews with uppercase : "
    f"{uppercase_mask.sum():,} "
    f"({uppercase_mask.mean()*100:.2f}%)"
)

print(
    f"Reviews with !         : "
    f"{exclamation_mask.sum():,} "
    f"({exclamation_mask.mean()*100:.2f}%)"
)

print(
    f"Reviews with ?         : "
    f"{question_mask.sum():,} "
    f"({question_mask.mean()*100:.2f}%)"
)

print(
    f"Reviews with digits    : "
```

```
    f"{digit_mask.sum():,} "
    f"({digit_mask.mean()*100:.2f}%)"
)
```

```
Reviews with uppercase : 0 (0.00%)
Reviews with !         : 0 (0.00%)
Reviews with ?         : 0 (0.00%)
Reviews with digits    : 4,178 (42.09%)
```

Preliminary inspection of the reviewContent field revealed that all review text had been lowercased prior to distribution, with zero instances of uppercase characters, exclamation marks, or question marks detected across all 9,926 reviews (0.0% in each case). Digit characters were present in 42.09% of reviews, confirming that numerical content was preserved. This preprocessing state has direct consequences for feature engineering: capitalisation-based features (such as ALL-CAPS intensity), punctuation density measures, and case-sensitive syntactic markers are uncomputable from this corpus and were therefore excluded from the feature set. All word-level, length-based, sentiment, and vocabulary features remain unaffected. This constraint is acknowledged as a limitation of the dataset distribution rather than the analytical approach, and is noted where relevant in the comparison with prior studies that operated on unprocessed review text

print("-" * 55)
for phrase in test_phrases:
    score = sid.polarity_scores(phrase)['compound']
    print(f"  {phrase:<43} {score:>+.3f}")
```

```
VADER SENSITIVITY TO APOSTROPHE STRIPPING
============================================================
Phrase                                        Compound
-------------------------------------------------------
  dont like this place at all                   -0.276
  don't like this place at all                  -0.276
  isnt great but ok                             -0.539
  isn't great but ok                            -0.539
  cant recommend this restaurant                -0.276
  can't recommend this restaurant               -0.276
```

The evaluation of VADER's approach to negation without apostrophes involved analyzing compound emotion scores for three corresponding contraction pairs: dont/don't, isnt/isn't, and cant/can't. Uniform compound scores were achieved across all three pairs, suggesting that the elimination of apostrophes does not hinder VADER's capacity to manage negation for these examined forms. This aligns with NLTK's VADER framework, which specifically incorporates both contracted forms and apostrophe-removed variations in its negation lexicon. No further amendments for these abbreviated contraction forms were thus necessary. Nonetheless, VADER ratings obtained from this corpus are still contingent upon the exclusion of capitalization and punctuation, which VADER utilizes as indicators of sentiment intensity.

EDA 6A.3—FUNCTION-WORD, PRONOUN & NEGATION PRESERVATION

In [97]:
```
# ═══════════════════════════════════════════════════════════
# EDA 6A.3 — FUNCTION-WORD, PRONOUN & NEGATION PRESERVATION
#

================================================================================
PRELIMINARY LEXICAL-NORMALISATION DIAGNOSTIC
================================================================================
Word families retaining multiple normal forms : 15/15

Preliminary interpretation:
Normal inflectional variants are widely preserved. This provides evidence against comprehensive global stemming or lemmatisation.
```

To assess whether the supplied review text had undergone systematic morphological normalisation, an inflectional-form preservation audit was conducted across 15 representative word families. All 15 families retained multiple naturally occurring inflectional variants. For example, order, orders, ordered, and ordering appeared as distinct tokens within the corpus, indicating that inflectional morphology had largely been preserved. This finding was reinforced by a Porter-stem signature audit. Highly frequent natural forms such as restaurants, delicious, and friendly occurred 682, 2,153, and 1,114 times respectively, whereas their corresponding Porter stems—restaur, delici, and friendli—were absent. Similarly, inflected forms such as waited, ordered, and loved co-occurred with their respective base forms rather than being systematically reduced to a common lemma. Taken together, these findings provide strong evidence against comprehensive corpus-wide stemming or lemmatisation. The supplied text is therefore best characterised as a substantially normalised representation in which casing and conventional punctuation have been removed, while lexical and inflectional structure remains largely intact. This has an important implication for subsequent theory-driven feature construction: dictionaries based on Reality Monitoring Theory and Interpersonal Deception Theory can operate on recognisable English lexical forms, but relevant morphological variants must either be represented explicitly or handled through a controlled and consistently documented normalisation procedure.

EDA 6A.5 — FINAL FEATURE COMPUTABILITY MATRIX

In [99]:
```python
# ═══════════════════════════════════════════════════════════
# EDA 6A.5 — FINAL FEATURE COMPUTABILITY MATRIX
#
# Objective:
# Consolidate evidence from EDA 6A.1–6A.4 and determine which
# text-derived features can be used validly in subsequent EDA
# and modelling.
#
# Status definitions:
# ✅ Usable
#    The required information survives preprocessing sufficiently
#    for the intended analysis.
#
# ⚠️ Usable with qualification
#    The feature is computable, but preprocessing changes its
#    interpretation or requires preprocessing-aware handling.
#
# ❌ Not recoverable
#    Required information was removed before analysis.
# ═══════════════════════════════════════════════════════════

From EDA 6A we have achieve below :

- analysing punctuation that had already been removed;
- interpreting zero capitalisation as reviewer behaviour;
- assuming first-person pronouns had been removed;
- missing split contractions in negation analysis;
- assuming the corpus had been stemmed;
- applying theory dictionaries without accounting for morphological variants;
- treating VADER scores as equivalent to sentiment from raw text.

final outcome : The text-integrity audit determined that the provided Yelp reviews are predominantly normalized instead of being authentic natural-language content. The casing and standard punctuation were methodically eliminated, obstructing the accurate reconstruction of style metrics reliant on capitalization, punctuation, and sentence boundaries. Nevertheless, the lexical substance,

function words, first-person pronouns, clear negation, and natural inflectional morphology were significantly maintained. No indications of extensive corpus-wide stemming or lemmatization were found. As a result, analyzes focused on word-level lexicon and theoretical linguistics are still viable, although measures sensitive to contractions, sentiment assessments, and morphology-dependent lexicons necessitate preprocessing considerations. These limitations were established prior to the ensuing linguistic examination and model creation to avert the misinterpretation of preprocessing artifacts as authentic language phenomena.

EDA 6B — Lexical Richness & Diversity

Our analytical objective is: Do genuine and fake-labelled reviews differ in lexical diversity after accounting for the substantial difference in review length?

In [100…

```
# ═══════════════════════════════════════════════════════════
# EDA 6B.1 — Token-Length Coverage and MATTR Window Selection
#
# Research objective: Determine what proportion of fake and
# genuine reviews meet each candidate window threshold, so that
# the MATTR window is selected on coverage evidence rather than
# convention.
#
# This cell is strictly diagnostic. The window decision is made
# after inspecting the output — not inside this code.

Before calculating MATTR, a coverage analysis was performed to determine a justifiable fixed window without relying on any observable class-level lexical diversity outcomes. Seven candidate windows, varying from 10 to 50 tokens, were assessed independently for authentic and counterfeit-labeled evaluations. Augmenting the window size resulted in increasingly significant class-specific attrition due to the systematic brevity of falsely labeled evaluations. A 15-token window preserved 94.4% of authentic reviews and 87.4% of falsely labeled reviews, resulting in an overall coverage of 90.9% and a class-coverage disparity of 7.0 percentage points. Expanding the window to 20 tokens diminished fake-review coverage to 81.4% and increased the class-coverage disparity to 9.4 percentage points, whereas a 25-token window preserved just 74.5% of fake-labeled reviews. A 15-token window was thus predetermined as the principal MATTR criterion, since it offered adequate fixed-window lexical context while minimizing overall attrition and the excessive removal of shorter counterfeit-labeled reviews. Reviews with less than 15 tokens were omitted from the main MATTR analysis instead of being given standard TTR values, as combining MATTR with length-dependent TTR would undermine comparability. MATTR-20 and MATTR-25 were preserved as sensitivity parameters to assess if ensuing results were valid across different window durations.

In [101…

```
# ======================================================================
# EDA 6B.2 — MATTR-15 Computation and Descriptive Distribution
#
# Window:
# 15 tokens, selected from coverage evidence in EDA 6B.1
# before examining any class-level MATTR results.
#
# Inclusion rule:
# Reviews with fewer than 15 tokens receive NaN and are excluded
# from the primary MATTR-15 comparison.
#
# Rationale:
# Falling back to standard TTR for short reviews would mix two
# different lexical-diversity measures and reintroduce review-
# length dependence in a class-dependent way.
#
# Inferential testing:
# Statistical inference and reviewer-dependence adjustment are
# deliberately deferred to EDA 6B.3.
# ======================================================================

# 2. Strict MATTR function
# ──────────────────────────────────────────────────────────

def mattr_strict(tokens, window=15):
    """
    Calculate Moving-Average Type-Token Ratio (MATTR)
    using a fixed window.

    For reviews with N >= window:
        1. Move a fixed-size window across the token sequence.
        2. Compute TTR within each window.
        3. Return the mean TTR across all windows.

    Reviews shorter than the selected window return NaN.

    No standard-TTR fallback is used because doing so would mix
    length-sensitive TTR with fixed-window MATTR.

DESCRIPTIVE GENUINE–FAKE MATTR-15 COMPARISON
================================================================================
Genuine median MATTR      : 0.9605
Fake median MATTR         : 0.9623
Median difference (Genuine - Fake)         : -0.0018

Genuine mean MATTR        : 0.9562
Fake mean MATTR           : 0.9561
Mean difference (Genuine - Fake)         : +0.0001

Descriptive interpretation : No meaningful class separation is apparent; mean MATTR values are virtually identical and the small median difference is in the opposite directio
n.

Note: Statistical inference and reviewer-level dependence adjustment are deferred to EDA 6B.3.
```

The descriptive MATTR results do not support a general lexical-diversity advantage for genuine reviews. However, MATTR is not a direct measure of the perceptual and contextual detail proposed by Reality Monitoring Theory; those theory-specific predictions are evaluated separately through targeted linguistic indicators in EDA 6C.

# ============================================================
# EDA 6B.2a — MATTR-15 DISTRIBUTIONAL COMPRESSION CHECK
#
# Research objective:
# Quantify the extent to which MATTR-15 scores are concentrated
# toward the upper bound of the scale.
#
# Substantial upper-bound compression could limit the
# discriminatory resolution of MATTR-15. Whether the negligible
# class difference is attributable to the short window is tested
# separately through the pre-specified MATTR-20 and MATTR-25
# sensitivity analyses in EDA 6B.2b.
#
# Analytical sample:
# Reviews containing >= 15 tokens.
# ============================================================

The MATTR-15 distributions exhibited significant clustering toward the upper limit of the scale. About 64.6% of authentic reviews and 65.1% of counterfeit-labelled reviews had MATTR values of no less than 0.95, whilst 6.8% and 10.4%, correspondingly, attained the peak value of 1.00. Both distributions exhibited significant negative skewness (Genuine = −1.45; Fake = −1.57), suggesting a concentration of high lexical-diversity values accompanied by extended lower tails. The concentration at the higher end was somewhat elevated in counterfeit-labeled evaluations, especially at thresholds of 0.98 and above. These findings indicate that the 15-token window offers restricted discriminating clarity within this corpus, although the main specification was preserved as it was chosen separately from the recorded class-level MATTR outcomes. Pre-determined sensitivity analyzes at 20 and 25 tokens were utilized to evaluate the resilience of the minimal class disparity against less condensed MATTR requirements.

EDA 6B.2b — PRE-SPECIFIED MATTR WINDOW SENSITIVITY ANALYSIS

In [106…

```
# ═══════════════════════════════════════════════════════════════
# EDA 6B.2b — PRE-SPECIFIED MATTR WINDOW SENSITIVITY ANALYSIS
#
# Objective:
# Assess whether the negligible MATTR-15 class difference and
# upper-bound compression are sensitive to the pre-specified
# alternative windows of 20 and 25 tokens.
#
# Comparison A — Window-specific eligible samples
#   MATTR-15: reviews >= 15 tokens
#   MATTR-20: reviews >= 20 tokens
#   MATTR-25: reviews >= 25 tokens
#
#   Sample composition changes with window size.
#   Results therefore reflect both:
#       (a) MATTR window specification
#       (b) changing sample eligibility
#
# Comparison B — Common restricted sample
#   Restrict all analyses to reviews >= 25 tokens.
#
#   The same observations are used for MATTR-15, MATTR-20,
#   and MATTR-25, isolating changes associated with window
#   specification from changes caused by sample selection.
#
# IMPORTANT:
# MATTR-15 remains the pre-specified PRIMARY specification.
# MATTR-20 and MATTR-25 are sensitivity analyses only.
```

```python

	Window	Mean difference (G-F)	Median difference (G-F)	Genuine >=0.99 (%)	Fake >=0.99 (%)	Genuine =1.00 (%)	Fake =1.00 (%)
0	15	-0.00014	-0.00148	9.09091	11.58553	4.19935	5.92875
1	20	0.00032	-0.00169	5.79142	7.07098	2.97647	3.97063
2	25	0.00098	-0.00154	4.10706	5.00408	2.42270	3.15475

```
EDA 6B.2b complete.
Interpret Comparison A and Comparison B jointly before proceeding to reviewer-aware inference in EDA 6B.3.
```

Sensitivity analysis was performed with predetermined MATTR intervals of 15, 20, and 25 tokens. Augmenting the window size significantly diminished upper-bound compression, as the percentage of authentic reviews exhibiting MATTR ≥ .99 decreased from 11.5% at window 15 to 4.1% at window 25, while the same percentage for counterfeit-labelled reviews dropped from 15.7% to 5.0%. Notwithstanding the improvement in measurement precision, disparities among classes persisted as minimal. In window-specific qualifying samples, the average genuine-minus-fake disparities varied from 0.0001 to 0.0010, and the median disparities ranged from −0.0015 to −0.0025. The equivalent outcome was reached when all three window specifications were assessed on a uniform limited sample of 8,011 reviews, each having a minimum of 25 tokens. These results suggest that the lack of significant lexical-diversity differentiation is consistent across various MATTR window selections and cannot be exclusively ascribed to upper-bound compression or alterations in sample eligibility.

EDA 6B.3 — REVIEWER-AWARE INFERENCE FOR MATTR-15

In [107…

```
# ============================================================
# EDA 6B.3 — REVIEWER-AWARE INFERENCE FOR MATTR-15
#
# Research objective:
# Quantify uncertainty around the genuine-fake-labelled
# MATTR-15 difference while accounting for repeated reviews
# contributed by the same reviewer.
#
# Primary specification:
# MATTR-15 only (pre-specified in EDA 6B.1).
#
# Analytical strategy:
#
# A. Cluster-robust OLS
#    - Estimates the review-level mean difference
#    - Standard errors clustered by reviewerID
#    - Provides conventional 95% CI and p-value
#
# B. Reviewer-cluster bootstrap
#    - Resamples reviewers with replacement
#    - Preserves reviewer multiplicity correctly
#    - All reviews from each sampled reviewer inherit the
#      reviewer's bootstrap multiplicity
#    - Estimates 95% percentile CIs for both mean and median
#      genuine-minus-fake differences
#
# Interpretation:
# Effect magnitude and confidence intervals are primary.
```

```python
# Statistical significance is secondary.
# ============================================================

import numpy as np
import pandas as pd

	Estimand	Observed difference	Reviewer-cluster bootstrap SE	95% CI lower	95% CI upper
0	Mean difference (Genuine - Fake)	0.000096	0.000731	-0.001322	0.001519
1	Median difference (Genuine - Fake)	-0.001793	0.000713	-0.003184	-0.000414

```
================================================================================
PRACTICAL MAGNITUDE ASSESSMENT
================================================================================
Absolute observed mean difference   : 0.000096
Absolute observed median difference : 0.001793
Standardised mean difference        : +0.0029

Interpretation rule:
Prioritise the magnitude and confidence intervals of the class difference. A statistically detectable difference should not automatically be interpreted as substantively impor
tant.

EDA 6B.3 complete.
```

Reviewer-aware inference was conducted for the primary MATTR-15 specification to account for repeated reviews contributed by the same reviewer (9,022 eligible reviews; 7,581 reviewer clusters). A reviewer-clustered ordinary least squares model estimated a mean genuine-minus-fake difference of +0.000096 (95% cluster-robust CI [−0.001325, +0.001517], p = .895). The corresponding standardised mean difference was 0.0029, indicating a substantively negligible effect. A reviewer-cluster bootstrap produced an almost identical estimate of uncertainty for the mean difference (95% percentile CI [−0.001322, +0.001519]), confirming the robustness of the result to reviewer-level dependence. The bootstrap median difference was −0.001793 (95% CI [−0.003184, −0.000414]), indicating a statistically detectable but extremely small tendency for fake-labelled reviews to have a higher median MATTR-15. This median asymmetry is consistent with the distributional compression identified in EDA 6B.2a, where fake-labelled reviews were somewhat more concentrated at the extreme upper end of the MATTR scale (15.7% versus 11.5% of genuine reviews at MATTR ≥ 0.99). However, the magnitude of the median difference remained analytically negligible. Furthermore, the pre-specified MATTR-20 and MATTR-25 sensitivity analyses produced similarly small class differences, including when all three window specifications were compared on the same ≥25-token sample. The persistence of the result as upper-bound compression decreased indicates that the negligible class separation was not simply an artefact of the 15-token window or differential sample eligibility. Collectively, the evidence indicates that MATTR provides little practically meaningful discrimination between genuine and fake-labelled reviews in this corpus. MATTR was therefore excluded from the Phase 1 engineered-feature set. Importantly, this result distinguishes review length from lexical diversity: although genuine reviews were substantially longer than fake-labelled reviews, this greater verbosity did not translate into greater local lexical diversity across any of the pre-specified MATTR windows examined.

EDA 6C.0A — CROSS-CONSTRUCT OVERLAP AND BLIND CONTEXTUAL AMBIGUITY AUDIT

In [108…

```
# ============================================================
# EDA 6C.0A — CROSS-CONSTRUCT OVERLAP AND
#             BLIND CONTEXTUAL AMBIGUITY AUDIT
#
# Research objective:
# Resolve lexical overlap and polysemy BEFORE freezing the
# theory-driven dictionaries and BEFORE examining class outcomes.
#
# IMPORTANT METHODOLOGICAL PRINCIPLES
#
# 1. Candidate terms were manually curated from theoretical
#    construct definitions and published linguistic-category
#    frameworks.
#
# 2. WordNet is used ONLY for controlled morphological
#    lemmatisation during matching.
#
# 3. WordNet was NOT used to generate candidate dictionary terms.
#
# 4. The original review text/token sequence is never altered.
#
# 5. Class labels are NOT examined anywhere in this cell.
```

```
#
# 6. Ambiguous terms are resolved using label-blind corpus
#    contexts before dictionaries are frozen.
# ============================================================

import numpy as np
import pandas as pd

WordNet candidate generation used        : NO
WordNet matching-time lemmatisation used : YES
Split-negation representations corrected : YES
Cross-construct overlap audit completed  : YES
Blind ambiguity audit completed          : YES

DO NOT freeze dictionaries yet.
Review the contextual evidence first, then assign each pending term as KEEP, EXCLUDE, or REASSIGN.
```

Linguistic characteristics based on theory were established prior to analyzing class-level results to minimize researcher flexibility and avert outcome-influenced dictionary creation. Candidate lexicons were meticulously assembled from the relevant theoretical ideas, although WordNet lemmatization was employed exclusively for regulated morphological alignment rather than for vocabulary creation. Due to the probable polysemy of many candidate words in restaurant-review discourse, a label-agnostic keyword-in-context evaluation was performed prior to finalizing the dictionaries. Ambiguous words that appeared often were preserved only if their usage in the corpus offered a consistently reliable representation of the construct; if not, they were either omitted or reallocated to a singular construct. For instance, feel/felt were omitted due to their conflation of sensory, emotional, and evaluative connotations, whereas cool was eliminated from the sensory vocabulary since it mostly conveyed a sense of general approbation or ambiance. In contrast, fresh and dry were preserved due to their primary use being tied to food. Subsequent to these determinations, there was no lemma-level intersection left among the principal sensory, spatial, temporal, cognitive, and uncertainty lexicons. Negation was addressed independently by canonicalized event matching to account for contractions disrupted during preprocessing. Crucially, all determinations about dictionary resolution were made independently of the Genuine/Fake classifications.

EDA 6C.0A — FINAL BLIND AMBIGUITY AUDIT

In [109…

```
# ============================================================
# EDA 6C.0A — FINAL BLIND AMBIGUITY AUDIT
#
# Objective:
# Audit the remaining potentially polysemous candidate terms
# before freezing the theory-driven dictionaries.
#
# Terms:
#   back  — spatial location vs "go back / come back"
#   hard  — physical texture vs difficulty/intensity
#   wait  — experienced waiting vs "can't wait"
#   quick — temporal speed vs broader evaluative use
#
# IMPORTANT:
# Class labels are NOT used anywhere in this cell.
# ============================================================

FINAL BLIND AUDIT COMPLETE
================================================================================
Class outcomes examined : NO
Dictionary freeze status: NOT YET

Review the contexts for back, hard, wait and quick before making the final KEEP/EXCLUDE decisions.
```

A contextual audit devoid of labels was performed prior to finalizing the theory-driven dictionaries to mitigate construct contamination from polysemous expressions. The audit revealed that several seemingly credible indicators failed to consistently reflect their intended concepts in restaurant-review discussions. For instance, "back" appeared more often in revisit phrases than in geographical descriptions, but "hard" typically denoted difficulty instead of food texture; hence, both were omitted from their potential constructions. Conversely, "quick" primarily denoted the pace of service or its length and was preserved as a temporal marker. The term "wait" was preserved as it often denoted actual waiting duration, although anticipatory phrases like "can't wait" were specifically omitted due to a predetermined sequencing requirement. Alongside previous clarifications of ambiguity, these determinations emphasized the specificity of constructs rather than the breadth of the vocabulary and were executed independently of review-class designations.

EDA 6C.0B — FINAL DICTIONARY FREEZE, LABEL-BLIND FEATURE COMPUTATION & CORPUS COVERAGE AUDIT

In [110…

```
# ═══════════════════════════════════════════════════════════
# EDA 6C.0B — FINAL DICTIONARY FREEZE,
#             LABEL-BLIND FEATURE COMPUTATION
#             & CORPUS COVERAGE AUDIT
#
# Research objective:
```

```
# Freeze and implement the theory-driven linguistic measurement
# system BEFORE examining Genuine/Fake class outcomes.
#
# This cell:
#   1. Freezes final construct dictionaries
#   2. Freezes ambiguity-resolution decisions
#   3. Verifies zero unintended cross-construct overlap
#   4. Implements matching-time lemmatisation
#   5. Implements special temporal "wait" exclusion rule
#   6. Implements canonical negation-event counting
#   7. Computes token-normalised feature densities
#   8. Audits corpus-wide coverage WITHOUT Class
#   9. Creates a reproducibility signature for the frozen spec
#
# IMPORTANT:
# Class labels are NOT examined anywhere in feature construction
# or corpus-coverage auditing.
#
# After this cell is completed successfully, dictionary content
# and matching rules must NOT be modified based on class results.
# ============================================================

✅ EDA 6C.0B COMPLETE.
Theory-driven dictionaries, matching rules, and feature definitions are now FROZEN.
Next step: EDA 6C.1 — Sensory and Perceptual Detail.
```

Subsequent to the label-agnostic dictionary evaluation, the conclusive linguistic assessment methodology was executed across all 9,926 reviews and 747,363 tokens devoid of class labels. All integrity assessments were successful, and no inadvertent lemma-level overlap persisted among the sensory, spatial, temporal, cognitive, and uncertainty frameworks. The corpus had considerable coverage across all intended indicators, varying from 32.18% of evaluations concerning uncertainty/hedging to 83.90% for total first-person self-reference, suggesting that future class comparisons will not be influenced by exceedingly rare language occurrences. The activation of the dictionary was comparably elevated, with 94.44–100% of frozen lemmas noted for four out of five lexical constructions and 98.36% for sensory language. Furthermore, the predetermined contextual guideline eliminated 236 anticipatory instances of "wait," hence diminishing the misclassification of future statements as experienced temporal data. The measuring criteria were thus finalized prior to the execution of any Genuine–Fake comparisons.

Do not interpret Reality Monitoring support until the observed direction and practical magnitude are reviewed.

✅ EDA 6C.1 computation complete.
```

Sensory/perceptual language displayed a subtle class distinction. Authentic-labelled reviews had a greater average sensory density compared to Fake-labelled reviews (1.784 vs 1.526 markers per 100 tokens), resulting in a mean difference of +0.258 (95% reviewer-clustered CI [0.127, 0.389], p < .001). A reviewer-cluster bootstrap generated a highly similar confidence interval [0.120, 0.388], supporting the resilience of the outcome against reviewer-level interdependence. Nonetheless, the standardized mean difference was minimal (0.078), suggesting restricted independent class differentiation. A clearer differentiation was observed in the frequency of sensory language: 58.92% of reviews marked as Genuine included at least one sensory indicator, in contrast to 42.21% of reviews labeled as Fake, resulting in a disparity of 16.72 percentage points; the odds ratio for reviewer clusters was 1.96 (95% CI [1.81, 2.13], p < .001). Notably, reviews characterized by sensory language revealed that Fake-labelled reviews had a higher sensory density compared to Genuine-labelled reviews (means 3.616 vs 3.028; medians 2.597 against 2.344). Consequently, the predominant factor behind the Genuine benefit was the more reliable availability of sensory information instead of heightened sensory intensity when such language was utilized. The results therefore offer conditional backing for the Reality Monitoring hypothesis regarding perceptual data, while revealing significant variability within the class and a restricted independent discriminative effect.

Spatial and temporal results are retained only as secondary decomposition analyses.
```

✅ EDA 6C.2 computation complete.

Contextual specificity generated a more varied pattern compared to sensory/perceptual language. The predetermined primary analysis revealed almost no disparity in the total spatial-temporal contextual density of Genuine- and Fake-labeled reviews (3.906 vs 3.853 markers per 100 tokens; mean difference = +0.053, 95% reviewer-clustered CI [−0.107, 0.212], p = .517). The standardized mean difference was minimal (0.013), and a reviewer-cluster bootstrap yielded a nearly comparable confidence range [−0.107, 0.212], indicating a lack of significant overall density differentiation. Nonetheless, contextual markers were more reliably found in Genuine-labelled reviews: 78.47% included at least one contextual marker, in contrast to 68.25% of Fake-labelled reviews, resulting in a disparity of 10.22 percentage points (reviewer-clustered OR = 1.70, 95% CI [1.54, 1.86], p < .001). Secondary decomposition revealed a little authentic benefit in spatial density (difference = +0.130, 95% CI [0.046, 0.214], p = .002; standardized difference = 0.063), but temporal density exhibited no significant class disparity (difference = −0.077, 95% CI [−0.206, 0.052], p = .242). Collectively, the results do not endorse a universal Genuine advantage in the amount of contextual information; instead, evaluations labeled as Genuine seem to more reliably incorporate contextual indicators, especially geographical data.

```

✅ EDA 6C.4 computation complete.

The incidence and severity of uncertainty/hedging language mirrored those of the sensory and cognitive dimensions. Authentic-labelled evaluations demonstrated a greater average density of uncertainty markers compared to fraudulent-labelled evaluations (0.654 vs 0.539 markers per 100 tokens), resulting in a mean difference of +0.115 (95% reviewer-clustered CI [0.067, 0.162], p < .001). A reviewer-cluster bootstrap produced a confidence interval that closely resembles [0.066, 0.163]. Nevertheless, the standardized mean difference was minimal (0.096), suggesting restricted independent class differentiation. A clearer differentiation was observed in prevalence: 38.39% of Genuine-labelled reviews had at least one uncertainty/hedging signal, in contrast to 25.89% of Fake-labelled reviews, resulting in a disparity of 12.51 percentage points (reviewer-clustered OR = 1.78, 95% CI [1.63, 1.95], p < .001). In contrast, reviews that included uncertainty language showed a higher density of Fake-labelled reviews compared to Genuine-labelled reviews (means 2.083 versus 1.704; medians 1.681 versus 1.370). Consequently, the overall Genuine benefit was mostly influenced by the more frequent appearance of uncertainty indicators rather than a heightened focus when such terminology was utilized. The results do not endorse the simplistic notion that Fake-labelled reviews consistently exhibit greater hedging language; rather, they uncover significant variability in its distribution among evaluations.

```

✅ EDA 6C.5 computation complete.

Self-referential language in the first person indicated a minor disparity among classes. Authentic-labelled reviews had a somewhat higher density of first-person references compared to Fake-labelled reviews (5.997 vs 5.794 markers per 100 tokens), resulting in a mean difference of +0.203 (95% reviewer-clustered CI [0.029, 0.376], p = .022). A bootstrap of reviewer clusters yielded a confidence range of [0.025, 0.378] that is nearly equivalent. Nonetheless, the standardized mean difference was minimal (0.048), suggesting considerable class overlap. First-person indicators were much more common in Genuine-labelled reviews (87.68% vs to 80.07%; difference = 7.61 percentage points; reviewer-clustered OR = 1.77, 95% CI [1.58, 1.99], p < .001). Secondary decomposition unveiled contrasting trends: individual self-reference was marginally elevated in Genuine-tagged reviews, whereas collective self-reference frequency was somewhat greater in Fake-tagged reviews. Moreover, across evaluations utilizing first-person language, Fake-labelled reviews had a higher total density of self-reference (7.236 compared to 6.839). These results suggest that variations in self-reference are minimal and structurally diverse, rather than indicative of a straightforward, class-wide pronoun trend.

The theory-based language examination yielded selective rather than consistent proof of class distinction. After the pre-definition of six principal construct-family assessments and the application of Holm correction for family-wise multiplicity, three constructs were found to be statistically distinct: sensory/perceptual language (Holm-adjusted p < .001), cognitive/process language (p = .014), and uncertainty/hedging (p < .001). All three demonstrated elevated token-normalized density in Genuine-labeled reviews, however the standardized mean differences were minimal (0.059–0.096), suggesting significant class overlap and little independent discriminative utility. The amalgamated spatial-temporal contextual density exhibited nearly no class differentiation, whilst first-person self-reference failed to maintain statistical distinction post-multiplicity correction, and expressive denial was also absent. Sensory/perceptual language yielded the most definitive outcome aligned with the Reality Monitoring hypothesis, which posits that authentic experiential narratives encompass more perceptual details, while the lack of a unified contextual-density variance suggests that the evidence for the theory was only partial rather than exhaustive. Analyzes of prevalence indicated a persistent pattern where Genuine-labelled reviews exhibited a higher frequency of including at least one marker from each language family compared to Fake-labelled reviews. Nonetheless, due to the significantly greater length of Genuine reviews, the variations in occurrences were approached with caution, and the main conclusion was derived from token-normalised density. In several constructs, marker-positive Fake-labelled reviews had higher conditional density; because to their reduced average length, these exclusively positive discrepancies were regarded as descriptive distributional patterns instead than indications of intentional linguistic focus. The findings suggest that the theory-based characteristics reveal statistically significant yet limited elements of language particular to classes and should be regarded as supplementary explanatory factors rather than independent markers of lying.

# EDA 6D — Class-Discriminative Lexical Patterns
#
# Research objective: Identify which specific word tokens most
# strongly discriminate between fake and genuine reviews at the
# corpus level, using the log-likelihood ratio (G² statistic).
#
# Why G² rather than raw frequency or TF-IDF difference:
# G² controls for the fact that common tokens appear frequently
# in both classes by chance. It measures whether a token's
# class distribution deviates significantly from what would be
# expected under independence — making it interpretable as a
# statistical claim rather than a frequency observation.
#
# Tokens are NOT pre-filtered by the theory-driven dictionaries
# from 6C. This cell is exploratory — it reveals what the data
# says without imposing theoretical expectations.

Source: Yelp Fake Review Dataset (Mukherjee et al., 2013). G² statistic measures deviation from independence — higher values indicate stronger class specificity. Rate expressed per 1,000 tokens within each class.

✅ EDA 6D chart saved at 300 dpi.

Class-discriminative lexical examination utilizing the log-likelihood ratio (G^2) statistic was employed on 5,138 vocabulary terms that appeared a minimum of 10 times throughout the aggregated corpus. G^2 served as an investigative ranking metric to pinpoint tokens with the most pronounced discrepancies in relative frequencies between Genuine- and Fake-labeled evaluations, rather than functioning as a comprehensive univariate significance assessment. The examination uncovered a distinct lexical disparity between the two benchmark categories, while also highlighting a methodologically significant source of dataset-specific information. The token with the highest G^2 value in Genuine-labelled reviews was alinea (G^2 = 252.7), succeeded by various venue- or entity-specific phrases such as publican, irazu, xoco, and achatz. These appropriate nouns do not represent broad language traits of authenticity; rather, their significance suggests that the lexical differentiation in the Yelp benchmark reveals disproportionate connections across specific restaurants, entities, and class classifications. This establishes a possible shortcut-learning system in which a bag-of-words classifier may partially recognize the benchmark context instead of acquiring transferable linguistic traits of fraudulent reviews.

Beneath this particular entity layer, a significantly interpretable lexical pattern was also apparent. Authentic-labelled evaluations were disproportionately linked to specific culinary terminology, encompassing pig, cheese, bacon, duck, chocolate, falafel, potato, and sauce. This aligns independently with the theory-based sensory/perceptual evaluation in EDA 6C, where Genuine-labelled reviews demonstrated markedly higher sensory density post-Holm correction, and corresponds with the Reality Monitoring hypothesis that firsthand accounts may encompass more perceptually rooted details. The exploratory lexical findings should be viewed as supplementary evidence instead of a direct autonomous validation of Reality Monitoring Theory. Conversely, top-ranked keywords connected with Fake encompassed more general category and evaluative phrases like excellent, cuisine, service, finest, location, and eatery. The disparity in item-specific vocabulary on the Genuine side vs the more generalized category-level vocabulary on the Fake-labelled side indicates a variation in lexical precision, although the corpus-level examination fails to identify the cognitive processes behind this distinction.

Counterfeit-labeled evaluations exhibited a heightened prevalence of terminology related to business relationships and service management, such as owner (G^2 = 218.9), manager (G^2 = 161.6), staff (G^2 = 120.8), customer (G^2 = 78.6), and customers (G^2 = 52.3). This suggests a heightened focus on engagements with the enterprise and its staff, rather than implying that such terminology is intrinsically misleading. Moreover, both very favorable descriptors (excellent, best) and highly unfavorable descriptors (worst, dreadful, horrible, unpleasant) were disproportionately linked to Fake-labeled reviews. This trend aligns with the previous rating assessment, which indicated heightened evaluative polarization in Fake-labeled evaluations as opposed to only a positive bias. It further supports the EDA 6C conclusion that Genuine-labelled reviews employ uncertainty and hedging indicators more reliably, although the lexical hierarchy alone cannot determine heightened psychological certainty or definitiveness among Fake reviewers.

Collectively, EDA 6D illustrates that the unconstrained vocabulary encompasses significant class-related information that surpasses the manually constructed, theory-driven features established in EDA 6C, thereby offering empirical support for the use of TF-IDF representations in Phase 1 classical modeling. Simultaneously, the importance of tokens particular to venues and entities presents a credible danger of shortcut learning tied to benchmarks and a possible inflating of prediction performance within the domain. This issue is fundamentally different from the previously noted reviewer-level dependence: the necessity for reviewer-disjoint and temporal evaluation persists in evaluating generalization across users and time, yet neither effectively isolates restaurant-specific lexical dependence due to significant restaurant overlap within those divisions. Thus, robust TF-IDF benchmark results need to be seen as indicative of in-domain predictive differentiation rather than as conclusive proof that the model has acquired transferable deceptive language. If necessary in Phase 1, the identification of the restaurant name offers a definitive justification for a focused sensitivity study on entity or restaurant robustness.

EDA 6E — MODELLING IMPLICATIONS & FEATURE REDUNDANCY

In [119…

# ═══════════════════════════════════════════════════════════════════════
# EDA 6E — MODELLING IMPLICATIONS & FEATURE REDUNDANCY
#
# Purpose:
# Convert the completed EDA into a defensible Phase 1 feature-governance
# architecture.
#
# This is NOT another class-comparison analysis.
# No new target-driven feature selection is performed here.
#
# EDA 6E answers:
#
# 1. Which variables must never enter predictors?
# 2. Which scalar engineered features are effectively redundant?
# 3. Which theory-driven features should proceed as an interpretable family?
# 4. Which behavioural/metadata features must remain conceptually separate?
# 5. What feature-family architecture should Phase 1 use?
#
# Key methodological principles:
#
# - CLEAN TRAINING / EDA CORPUS ONLY
# - IDs retained only for grouping, splitting and diagnostics
# - Six frozen 6C constructs retained regardless of univariate Holm outcome
# - MATTR-15 excluded based on the pre-modelling EDA 6B conclusion
# - Spearman correlation used because many scalar variables are skewed
# - |rho| >= .90 is a NEAR-REDUNDANCY FLAG, not a universal deletion rule
# - TF-IDF hyperparameters are NOT tuned or selected in EDA
# ═══════════════════════════════════════════════════════════════════════

import numpy as np
import pandas as pd

# ═══════════════════════════════════════════════════════════════════════
# 0. WORKING DATA
# ═══════════════════════════════════════════════════════════════════════

# IMPORTANT:
# lexical_data contains the frozen 6C theory-driven features.
# Therefore it is the correct dataframe for the 6E audit.

```
================================================================================================
SECTION K — TF-IDF GOVERNANCE
================================================================================================
TF-IDF representation        : LOCKED
Exact min_df/max_df          : NOT locked in EDA
Exact vocabulary size        : NOT locked in EDA
Regularisation parameters    : NOT locked in EDA
Model hyperparameters        : selected using training-only CV
Supplied test set            : NEVER used for feature/hyperparameter selection

Interpretation:
Strong TF-IDF performance represents in-domain lexical discrimination. It must not automatically be interpreted as transferable deception detection because EDA 6D identified v
enue/entity-specific lexical signal.

================================================================================================
SECTION L — VALIDATION INTERPRETATION
================================================================================================
Reviewer-disjoint evaluation:
  Tests generalisation to previously unseen reviewers.

Temporal forward evaluation:
  Tests generalisation across time / temporal drift.

Important restaurant-shortcut caveat:
  Neither reviewer-disjoint nor temporal evaluation directly isolates restaurant-name dependence because substantial restaurant overlap remains across those partitions.

Therefore:
  A later targeted restaurant/entity sensitivity analysis may be justified if Phase 1 TF-IDF performance suggests that the shortcut-learning concern materially affects interpr
etation.

================================================================================================
EDA 6E COMPUTATION COMPLETE
================================================================================================

Stored outputs:
  PHASE1_FEATURE_GOVERNANCE
  PHASE1_MODEL_FAMILIES
  PHASE1_STRUCTURAL_FEATURES
  PHASE1_THEORY_FEATURES
  PHASE1_BEHAVIOURAL_FEATURES
  PHASE1_REDUNDANCY_FLAGS

Feature-family architecture:
  A — TF-IDF lexical
  B — Theory / linguistic
  C — Behaviour / metadata
  D — Combined

IMPORTANT:
  Feature-family architecture is locked.
  Exact modelling hyperparameters are NOT locked.
  They will be selected inside training-only validation.

NEXT:
  Interpret Sections D–H, confirm the final redundancy decisions, write the 6E synthesis, and formally close EDA.
```

Before the redundancy assessment, target, identifier, and administrative variables — such as reviewID, reviewerID, restaurantID, reviewer name, location, raw review and account-creation dates, along with the partition label — were irrevocably omitted from model predictors and preserved solely for purposes of grouping, temporal division, feature development, diagnostics, and validation. The feature-redundancy audit subsequently pinpointed an almost flawless structural cluster consisting of ReviewLength, character count, and unique-word count, with every pairwise Spearman correlation over .995. These factors thus signified fundamentally the same underlying dimension of review length. ReviewLength was maintained as the sole verified structural predictor, although character count and unique-word count were omitted from predictive modeling due to their redundancy.

Reviewer behavioral variables demonstrated a secondary, more extensive correlation cluster. Metrics such as review count, useful votes, cool votes, funny votes, compliments, friends, and fans were significantly interconnected, suggesting that they reflect overlapping yet conceptually distinct facets of reviewer behavior, involvement, and social standing. The most robust correlation was between usefulCount and coolCount (ρ=.915), above the predetermined near-redundancy limit. Both were however preserved inside the different behavioral/metadata feature category as they signify unique platform-engagement metrics, and the modeling aim is predictive comparison rather than succinct coefficient estimate. Their robust association will thus be clearly acknowledged when analyzing coefficients or SHAP values, since predictive significance may be allocated among correlated variables. Other behavioral connections were significant however stayed within the exclusion threshold and were preserved for multivariate analysis.

The theory-based language representation exhibited no similar near-redundancy. None of the six principal 6C constructions attained the predetermined criterion of $|\rho| \geq .90$ with any other major construct, signifying that they were not just numerical replicas. As a result, Model B preserved sensory, contextual, cognitive, uncertainty, first-person self-reference, and negation densities. Crucially, retention relied on the predetermined theoretical framework instead of univariate statistical significance; conceptions that failed to meet Holm adjustment criteria were not subsequently excluded. Secondary first-person and spatial-temporal decompositions were solely illustrative, steering clear of redundant representations of their associated aggregate notions. MATTR-15 was omitted from all model families after EDA 6B, since the average class difference was just +0.000096 with a standardized effect of 0.003, signifying an absence of practically significant class-separating data.

These choices resulted in a four-family Phase 1 modeling framework that includes an unconstrained TF-IDF lexical model, a theory-based linguistic model, a behavioral/metadata model, and an integrated model. The distinction is analytically significant as each family embodies a unique interpretation risk. The lexical framework may utilize the venue- and entity-specific shortcut indicators recognized in EDA 6D, whilst behavioral variables might include the identity structure of reviewers and traits linked to Yelp's filtering and label-creation mechanism. Evaluating the feature families independently prior to their integration will elucidate not only which models most effectively differentiate the benchmark labels, but also which information source enhances that predictive capability. The precise TF-IDF vocabulary controls, regularization parameters, and classifier hyperparameters were intentionally omitted from the exploratory data analysis and will be determined using validation solely on the training data, with the provided test set excluded from all feature and hyperparameter choices.

The resultant feature-governance approach therefore differentiates prediction efficacy from meaningful interpretation. Robust results from Model A will signify in-domain lexical differentiation; nevertheless, they will not, on their own, prove transferable deception detection due to the restaurant/entity artifact noted in EDA 6D. Similarly, robust results from Model C will illustrate the predictive significance of reviewer and platform information, however they must be analyzed with caution due to the reviewer-level framework already outlined in the EDA. The reviewer-disjoint and temporal holdout evaluations will evaluate generalization to unfamiliar reviewers and over time; yet, neither method directly separates restaurant-specific lexical reliance due to significant overlap among restaurants in those divisions. A focused sensitivity study of the restaurant/entity may be deemed necessary in Phase 1 if the performance of the lexical model suggests that this shortcut-learning issue significantly impacts interpretation.

Phase 1: Classical ML Benchmark

To establish a reproducible, leakage-controlled classical ML benchmark on the Yelp dataset, determine which information source drives detection performance, evaluate robustness across reviewer and temporal shifts, and freeze the classical reference models required for subsequent transformer and explainability comparisons.

PHASE 1 — CELL 1 REPRODUCIBILITY CONFIGURATION, DATA FREEZE, AND VALIDATION ARCHITECTURE

In [122…

```
# ═══════════════════════════════════════════════════════════════════════
# PHASE 1 — CELL 1
# REPRODUCIBILITY CONFIGURATION, DATA FREEZE,
# AND VALIDATION ARCHITECTURE
#
# PURPOSE
# -------
# Establish the immutable foundation for Phase 1 before any model is fitted.
#
# RULES
# -----
# 1. No evaluation set is used for feature selection or hyperparameter tuning.
# 2. All feature-family decisions were locked during EDA.
# 3. Reviewer identity is never a predictor.
# 4. Reviewer identity IS used for group-aware cross-validation and inference.
# 5. Regimes A/B use the full clean supplied training set.
# 6. Regimes C/D use historical pre-2011 training observations only.
# 7. Exact TF-IDF/model hyperparameters are selected inside training-only CV.
# 8. Supplied benchmark labels are Yelp filter/proxy labels, not unquestionable
#    human-verified deception ground truth.

# 14. GROUP-AWARE CROSS-VALIDATION
#
# Why reviewer groups?
#
# EDA established reviewer-level dependence and strong reviewer label purity.
#
# Using ordinary StratifiedKFold would allow reviews from the same reviewer
# to appear in both CV training and validation folds.
#
# We therefore use StratifiedGroupKFold for training-only model selection.
# ReviewerID is a GROUPING VARIABLE, never a predictor.
# ============================================================================

================================================================================
PHASE 1 — REPRODUCIBILITY CONFIGURATION
================================================================================
Python       : 3.12.13
NumPy        : 2.0.2
Pandas       : 2.3.3
SciPy        : 1.16.3
Scikit-learn : 1.6.1

Master random seed : 42
Bootstrap reps     : 2,000
CV folds           : 5

NOTE: RANDOM_STATE will be passed explicitly to every stochastic estimator/resampling procedure that supports it.

================================================================================
RAW DATA INTEGRITY
================================================================================
Raw train rows : 9,929
Raw test rows  : 2,483
Train missing reviewContent : 3
Test missing reviewContent  : 0

================================================================================
FROZEN MODELLING DATA
================================================================================
Clean train rows : 9,926
Clean test rows  : 2,483

TARGET
--------------------------------------------------------------------------------
Column     : flagged
Class 0    : Genuine / Recommended
Class 1    : Fake-labelled / Filtered / Suspicious proxy label
Binary check: PASSED

Train — Genuine: 4,993 | Fake: 4,933
Test  — Genuine: 1,212 | Fake: 1,271

Account-age reconstruction : PASSED

================================================================================
PERMANENT PREDICTOR EXCLUSIONS
================================================================================
flagged, Class, reviewID, reviewerID, restaurantID, name, location, date, yelpJoinDate, split

================================================================================
LOCKED FEATURE FAMILIES
================================================================================
Model A : TF-IDF from 'reviewContent'
          Classifiers = Logistic Regression / LinearSVC / Multinomial NB

Model B : ReviewLength + 6 frozen theory constructs
          ['ReviewLength', 'sensory_density', 'context_density', 'cognitive_density', 'uncertainty_density', 'fp_all_density', 'negation_density']

Model C : 13 behavioural / metadata features
          usefulCount AND coolCount retained; their correlation is handled during interpretation.

Model D : A + B + C combined

================================================================================
VALIDATION ARCHITECTURE — VERIFIED AGAINST EDA
================================================================================

PHASE 1—CELL 2 EXACT RECONSTRUCTION OF FROZEN EDA 6C THEORY FEATURES

In [132…

```
# ═══════════════════════════════════════════════════════════════════════
# PHASE 1 — CELL 2
# EXACT RECONSTRUCTION OF FROZEN EDA 6C THEORY FEATURES
#
# PURPOSE
# -------
# Reconstruct the theory-driven linguistic features used in EDA 6C
# EXACTLY from the original frozen EDA 6C.0B specification.
#
# SOURCE OF TRUTH
# ---------------
# Original EDA 6C.0B:
# FINAL DICTIONARY FREEZE, LABEL-BLIND FEATURE COMPUTATION
# & CORPUS COVERAGE AUDIT
#
# PRINCIPLES
# ----------
# 1. No class labels are used in feature construction.
# 2. reviewContent is never altered.
# 3. WordNet is used ONLY for matching-time lemmatisation.

PHASE 1 — CELL 3 (CORRECTED) Frozen Preprocessing Pipelines and Hyperparameters Search Spaces

In [136…

```python
# ============================================================
# PHASE 1 — CELL 3 (CORRECTED)
# Frozen Preprocessing Pipelines and Hyperparameter Search Spaces
#
# Corrections applied:
# 1. MNB uses normal TF-IDF — non-negative already
# 2. Model D fully defined here via ColumnTransformer
# 3. LR uses log1p on skewed features before StandardScaler
# 4. class_weight removed — data balanced, Macro-F1 sufficient
# 5. n_jobs=1 in RF/XGBoost — GridSearchCV parallelises
# 6. No warnings suppression; use_label_encoder removed
# 7. lowercase=False, strip_accents removed (corpus pre-lowercased)
```

```python
# 8. Computational burden reports 2× for both training origins
# ═══════════════════════════════════════════════════════════════

CELL 3 — FROZEN. All pipelines and grids defined.
======================================================================
  A: LR · LinearSVC · MNB  (TF-IDF)
  B: LR · RF · XGBoost     (theory features)
  C: LR · RF · XGBoost     (behavioural features)
  D: LR · LinearSVC        (combined ColumnTransformer)

  NEXT: Cell 4 — fit and evaluate all models
```

PHASE 1 — CELL 4A TRAINING-ONLY REVIEWER-GROUPED CV HYPERPARAMETER SEARCH

In [137…

```python
# ======================================================================
# PHASE 1 — CELL 4A
# TRAINING-ONLY REVIEWER-GROUPED CV HYPERPARAMETER SEARCH
#
# PURPOSE
# -------
# Tune all 11 pre-specified classical algorithms using TRAINING DATA ONLY.
#
# STRICT GOVERNANCE
# -----------------
# 1. NO held-out Regime A/B/C/D data accessed.
# 2. NO held-out predictions produced.
# 3. NO bootstrap inference.
# 4. NO family winner selected here.
# 5. NO algorithm/grid/preprocessing changes allowed after results are seen.
# 6. Hyperparameters selected solely by reviewer-grouped CV Macro-F1.
#
# TRAINING ORIGINS
# ----------------
# Full:
#     train_full
#     Later evaluation → Regimes A and B
#
# Historical:
#     train_temporal
#     Later evaluation → Regimes C and D
#
# OUTPUT
# ------
# 22 searches:
#     11 algorithms × 2 training origins
#
# For each:
#     • best mean CV Macro-F1
#     • CV SD
#     • five fold-level Macro-F1 scores
#     • selected hyperparameters
#     • runtime
#     • fitted best estimator
#
# Cell 4B will determine family winners BEFORE held-out evaluation.

✓ CV results saved
✓ CV fold audit saved
✓ Best hyperparameters saved
✓ CV partition signatures saved

================================================================================
PHASE 1 CELL 4A — COMPLETE
================================================================================
✓ 22 training-only CV searches completed
✓ Exact reviewer-grouped folds frozen per origin
✓ Zero reviewer overlap verified in every CV fold
✓ Same CV folds used by every algorithm within each origin
✓ Macro-F1 used as sole hyperparameter-selection metric
✓ Five fold-level scores retained for every selected configuration
✓ Selected hyperparameters retained machine-readably
✓ Fitted best estimators retained
✓ CV partition fingerprints retained
✓ No family winner selected
✓ No held-out Regime A/B/C/D data accessed
✓ No held-out predictions generated
✓ No bootstrap inference performed

HYPERPARAMETERS ARE NOW FROZEN.
Do NOT alter algorithms, grids, preprocessing or selected parameters based on subsequent results.

NEXT:
PHASE 1 CELL 4B — determine family winners, freeze the primary RQ1 classical comparator and freeze the strongest overall classical system, using CV results ONLY.
```

In the high-dimensional combined feature space, convergence warnings were produced by the initial Model D LR and LinearSVC searches. As a result, their CV scores are regarded as tentative. Prior to Model D selection, the identical frozen models, hyperparameter grids, CV folds, and scoring criteria will be performed with a higher optimization iteration ceiling. Instead of post-hoc model modification, this is numerical convergence remediation.

PHASE 1 — CELL 4A-R MODEL D CONVERGENCE REMEDIATION

In [138…

```python
# ============================================================================
# PHASE 1 — CELL 4A-R
# MODEL D CONVERGENCE REMEDIATION
#
# PURPOSE
# -------
# Re-run ONLY the four Model D searches after increasing the numerical
# iteration ceiling.
#
# NOTHING substantive changes:
# - same feature architecture
# - same algorithms
# - same C grid
# - same TF-IDF grid
# - same preprocessing
# - same frozen CV folds
# - same Macro-F1 selection criterion
#
# This is numerical convergence remediation only.
# ============================================================================

7	Historical	D	LinearSVC	0.9024	0.0051	Hist_D_LinearSVC	C, D

```
================================================================================
SECTION 4 — CV PERFORMANCE TIER SUMMARY
================================================================================

Tier 1 — Behavioural / metadata (Model C)
  Full       : XGBoost     Macro-F1 = 0.8868 (SD 0.0055)
  Historical : XGBoost     Macro-F1 = 0.9055 (SD 0.0062)

  Interpretation:
  Reviewer/platform metadata carries a very strong signal associated
  with the supplied Yelp labels. This should not be interpreted as
  evidence that the behavioural variables are universally transferable
  indicators of deception.

Tier 2 — Combined representation (Model D)
  Full       : LinearSVC   Macro-F1 = 0.8850 (SD 0.0057)
  Historical : LinearSVC   Macro-F1 = 0.9024 (SD 0.0051)

  Interpretation:
  The combined representation does not improve internal CV performance
  over Model C alone. The small differences are descriptive only.
  The pattern is consistent with behavioural information carrying much
  of the predictive signal, but held-out evaluation is required before
  drawing a stronger conclusion.

Tier 3 — TF-IDF lexical text (Model A)
  Full       : LR          Macro-F1 = 0.6869 (SD 0.0159)
  Historical : LinearSVC   Macro-F1 = 0.6795 (SD 0.0158)

  Interpretation:
  Text-only prediction is substantially weaker than behavioural
  prediction. Internal CV performance is similar across the two
  training origins; temporal stability is NOT inferred here.

Tier 4 — Theory-driven linguistic features (Model B)
  Full       : RF          Macro-F1 = 0.6042 (SD 0.0090)
  Historical : RF          Macro-F1 = 0.6054 (SD 0.0222)

  Interpretation:
  Theory-only features provide limited standalone discrimination.
  This is compatible with the small standardized effects observed
  during EDA 6C. Fold-to-fold variability is substantially greater
  within the Historical-origin CV results.

✓ Strongest Historical-origin classical model frozen

NEXT: PHASE 1 CELL 5 — FIRST HELD-OUT EVALUATION.
```

Classical model selection was conducted exclusively using five-fold reviewer-grouped cross-validation on the training data, with Macro-F1 designated as the selection criterion and all held-out evaluation regimes withheld from model selection. Behavioural and platform metadata (Model C) provided the strongest predictive performance, with XGBoost achieving mean CV Macro-F1 scores of 0.887 and 0.906 for the Full and Historical training origins, respectively. In contrast, the best TF-IDF text-only models achieved 0.687 using Logistic Regression for the Full origin and 0.679 using LinearSVC for the Historical origin, while theory-driven linguistic features produced substantially lower standalone discrimination of approximately 0.60 Macro-F1. Combining lexical, theory-driven and behavioural information (Model D) did not improve mean cross-validation performance relative to behavioural metadata alone. These findings indicate that the supplied Yelp labels contain a particularly strong behavioural and platform-related predictive signal; however, this should not be interpreted as evidence that these variables constitute transferable indicators of deceptive reviewing behaviour, given that their predictive power may partly reflect structural characteristics of Yelp's filtering and labelling process. For subsequent transformer comparisons, Full-origin TF-IDF Logistic Regression (Macro-F1 = 0.687) was frozen as the primary classical comparator to preserve information equivalence between text-based classical and transformer models. XGBoost using behavioural metadata was separately retained as the strongest overall classical system. All model-selection decisions were frozen prior to held-out evaluation.

NEXT: Cell 5B — FIRST FROZEN HELD-OUT PREDICTIONS AND DESCRIPTIVE PERFORMANCE EVALUATION.
```

Cell 5A passed exactly as intended. We now know that the held-out state is intact, the four regime sizes reproduce the frozen design, the labels exist both inside the frames and as separate regime_*_y objects, and all eight already-fitted winners are available.

So we can move to the first actual held-out evaluation (Phase 1 - Cell 5B).

PHASE 1—CELL 5B—FIRST HELD-OUT EVALUATION OF FROZEN CLASSICAL WINNERS

In [143…

```
# ================================================================================
# PHASE 1 — CELL 5B
# FIRST HELD-OUT EVALUATION OF FROZEN CLASSICAL WINNERS
#
# PURPOSE
# -------
# Evaluate the 8 frozen family winners on their pre-specified held-out regimes.
#
# FULL-origin winners:
#     Regime A — supplied benchmark
#     Regime B — unseen-reviewer benchmark subset
#
# HISTORICAL-origin winners:
#     Regime C — forward temporal
#     Regime D — forward temporal + unseen reviewer
#
# STRICT RULES
# ------------
# — NO model fitting
# — NO hyperparameter tuning
# — NO model reselection
# — NO bootstrap inference in this cell
# — Macro-F1 remains the PRIMARY metric
#
# OUTPUTS
# -------
```

```
# — Macro-F1
# — Accuracy
# — Balanced accuracy
# — Per-class precision / recall / F1 / support
# — Confusion matrices
# — Row-level predictions retained for later bootstrap inference
# ============================================================================

```

Held-out evaluation largely reproduced the performance hierarchy observed during reviewer-grouped cross-validation and provided little evidence that the Full-origin CV estimates were materially optimistic for the conventional Yelp benchmark. On the supplied benchmark (Regime A), the behavioural/metadata XGBoost model achieved the highest Macro-F1 (0.889), closely matching its grouped-CV estimate of 0.887, while the TF-IDF Logistic Regression text baseline achieved 0.689 compared with 0.687 in CV. The combined LinearSVC and theory-driven Random Forest achieved Macro-F1 scores of 0.878 and 0.599, respectively. Restricting the benchmark to previously unseen reviewers (Regime B) produced relatively modest reductions across all feature families. The text-only model declined by 1.6 percentage points to 0.673, whereas the behavioural and combined models each declined by approximately 2.0 percentage points, to 0.870 and 0.858, respectively. Although this descriptive reduction is consistent with some reviewer-associated contribution to benchmark performance, the behavioural model's retained Macro-F1 of 0.870 indicates that shared reviewer identity is not the only source of predictive signal. Forward temporal evaluation produced a more pronounced change for the metadata-rich models. Historical-origin behavioural XGBoost and combined LinearSVC achieved Macro-F1 scores of 0.847 and 0.848 in Regime C, compared with internal grouped-CV estimates above 0.90 obtained on the same pre-2011 training data, whereas the weaker text-only and theory-driven models showed much smaller descriptive CV-to-forward differences. The behavioural and combined models were also numerically almost indistinguishable in the forward regimes: their Macro-F1 scores differed by only 0.001 in Regime C and less than 0.001 in Regime D, providing no descriptive evidence that the selected combined-family model offered a practically meaningful advantage over the selected behavioural-family model. Adding the unseen-reviewer restriction within the forward period produced only a further modest reduction, with behavioural and combined models retaining Macro-F1 scores of 0.837 and 0.838 in Regime D. Class-specific results additionally revealed a persistent prediction asymmetry in the metadata-rich models. Behavioural XGBoost consistently achieved substantially higher recall for Fake than Genuine reviews—for example, 0.927 versus 0.851 in Regime A, 0.946 versus 0.779 in Regime B, and 0.929 versus 0.745 in Regime D—indicating that its strong overall performance was accompanied by a materially higher tendency to misclassify Genuine reviews as Fake under the more demanding evaluation conditions. Overall, these findings indicate that reviewer/platform metadata provides the strongest predictive signal for the supplied Yelp labels and retains substantial predictive value beyond previously observed reviewers, but that this signal appears more temporally sensitive than the weaker lexical representation and may continue to reflect structural characteristics of Yelp's filtering and labelling process. These conclusions remain descriptive pending reviewer-cluster bootstrap confidence intervals and paired inferential comparisons.

NEXT: interpret Cell 5C and integrate inference with the frozen Cell 5B descriptive findings.
```

Reviewer-cluster bootstrap confidence intervals were computed for all sixteen held-out Macro-F1 estimates using 2,000 bootstrap replicates with reviewers as the resampling unit. Interval widths were consistent with the reviewer-cluster structure of the evaluation samples, with the reviewer-disjoint Regime B generally producing the widest uncertainty intervals and the larger forward-evaluation samples producing comparatively narrower intervals. Within every regime, the confidence intervals for text-only and theory-driven models were clearly separated from those of the behavioural and combined models, reinforcing the substantial descriptive performance difference between these model families. Formal inference was conducted using eight paired comparisons defined and frozen after completion of the descriptive held-out evaluation but before inferential calculations: Behavioural minus Text and Combined minus Behavioural across each of the four evaluation regimes. Effect sizes were estimated using paired reviewer-cluster bootstrap confidence intervals, while hypothesis tests used reviewer-cluster paired permutation tests with Holm correction across the full eight-comparison family.

The Behavioural minus Text contrast was statistically supported under Holm correction in all four regimes. Macro-F1 advantages ranged from +0.171 in Regime D to +0.201 in Regime A, with all reviewer-cluster bootstrap confidence intervals excluding zero. The corresponding raw permutation p-values reached the minimum attainable with 5,000 permutations (approximately .0002), producing Holm-adjusted p-values of .0016 in all four regimes. These results provide consistent evidence that reviewer and platform metadata substantially outperformed the corresponding TF-IDF text-only representation as a predictor of the supplied Yelp labels under conventional benchmark, reviewer-disjoint, forward-temporal, and combined forward-plus-unseen-reviewer evaluation.

The selected Combined-family model did not demonstrate a statistically supported advantage over the selected Behavioural-family model in any regime. In Regimes A and B, the combined model achieved slightly lower Macro-F1, with differences of approximately −0.011 and −0.012; although the unadjusted paired bootstrap intervals narrowly excluded zero, these contrasts did not survive Holm correction ($p_{\mathrm{Holm}}=.053$) and .098, respectively). In Regimes C and D, the differences were effectively zero, with confidence intervals spanning zero and Holm-adjusted p-values of 1.00. Accordingly, the results provide no evidence that the selected combined-family system materially improves upon the selected behavioural-family system. Because the two families also use different selected algorithms, these comparisons should not be interpreted as isolating the causal contribution of adding lexical and theory-driven features.

PHASE 1 — CELL 5D — FINAL SYNTHESIS AND FREEZE

```
================================================================================================
SECTION 2 — NINE FROZEN PHASE 1 CONCLUSIONS
================================================================================================

C1: Grouped-CV estimates transferred closely to the conventional Yelp benchmark
Status: Descriptive
Evidence: For Full-origin family winners, the absolute difference between reviewer-grouped CV and Regime A held-out Macro-F1 was approximately 0.002 for Models A and C and rem
ained within approximately 0.007 for all four families. This provides little evidence of material CV optimism on the conventional benchmark.

C2: Behavioural metadata substantially outperforms text across all four evaluation regimes
Status: Inferentially supported
Evidence: Behavioural minus Text ΔMacro-F1 ranged from +0.171 to +0.201 across Regimes A–D. All four reviewer-cluster bootstrap confidence intervals excluded zero and all four
Holm-adjusted reviewer-cluster permutation p-values were .0016.

C3: The selected combined-family model showed no Holm-corrected advantage over the selected behavioural-family model
Status: Inferentially supported
Evidence: Combined minus Behavioural ΔMacro-F1 ranged from approximately -0.012 to +0.001. No comparison survived Holm correction. In Regimes C and D the differences were effe
ctively zero, while Regimes A and B numerically favoured the behavioural-family winner by approximately 1.1 percentage points.

C4: Metadata-rich models showed a larger descriptive forward-generalisation gap than the text-only model
Status: Descriptive
Evidence: Historical-origin Model C achieved grouped-CV Macro-F1 = 0.9055 but Regime C forward Macro-F1 = 0.8470, a descriptive difference of -0.0585. Historical-origin Model
A changed from 0.6795 in grouped CV to 0.6713 in Regime C, a difference of -0.0082. This pattern is consistent with greater temporal sensitivity of the behavioural/platform si
gnal, although internal CV and forward held-out evaluation use different evaluation structures and the difference was not itself subjected to paired inference.

C5: Theory-driven linguistic features have limited standalone predictive value but remain theoretically informative
Status: Descriptive / replicated
Evidence: Model B remained approximately 0.57–0.60 Macro-F1 across held-out regimes. This is consistent with the small standardised differences observed for the significant ED
A 6C constructs (approximately 0.059–0.096). Statistically detectable linguistic associations therefore did not translate into strong standalone individual-level classificatio
n performance.

C6: Behavioural predictive strength remains high among previously unseen reviewers
Status: Mixed: descriptive subset contrast + inferential paired model evidence
Evidence: Model C decreased descriptively from Macro-F1 = 0.889 in Regime A to 0.870 in the unseen-reviewer Regime B. The Behavioural minus Text advantage remained large in Re
gime B (ΔMacro-F1 = +0.197, 95% reviewer-cluster bootstrap CI [+0.171, +0.223], Holm-adjusted p = .0016). Shared reviewer identity is therefore not necessary for the behaviour
al representation to retain a strong predictive advantage, although A→B remains a descriptive nested-subset comparison rather than a causal estimate of reviewer-overlap effect
s.

C7: High metadata-rich Macro-F1 masks persistent Fake/Genuine recall asymmetry
Status: Descriptive
Evidence: For Models C and D, Fake recall exceeded Genuine recall by approximately 8–20 percentage points across the four regimes. For Model C in Regime D, Fake recall was 0.9
29 compared with Genuine recall of 0.745. The asymmetry increased descriptively under the harder evaluation conditions and is practically relevant because a meaningful share o
f Genuine reviews were classified as Fake.

C8: The primary RQ1 classical comparator is Full-origin Model A Logistic Regression
Status: Frozen methodological decision
Evidence: On Regime A, Full Model A Logistic Regression achieved Macro-F1 = 0.6885 with a reviewer-cluster 95% CI of [0.6695, 0.7056]. It is retained as the primary classical
comparator for Phase 2 because it uses review text only and is therefore information-equivalent to text-based transformer models.

C9: Strong Yelp benchmark performance should not be interpreted as evidence of universally transferable deception detection
Status: Interpretive limitation
Evidence: The high predictive performance of Model C demonstrates a strong association between reviewer/platform metadata and the supplied Yelp labels. However, Yelp's filteri
ng labels are treated as proxy labels rather than unambiguous ground-truth deception labels. Temporal sensitivity and class-recall asymmetry are compatible with platform-speci
fic label-generation structure and therefore warrant caution when interpreting the signal as transferable deceptive-review behaviour.

================================================================================================
SECTION 3 — WHAT PHASE 1 DID NOT ESTABLISH
================================================================================================

1. That reviewer behavioural variables are causally related to deceptive reviewing behaviour.

2. That temporal performance changes are caused by a specific mechanism such as distribution shift or evolution of Yelp's filtering process.

3. That Model A fails to detect deception. Its lower predictive performance only shows that the supplied Yelp labels are more predictable from the selected reviewer/platform m
etadata than from the frozen TF-IDF text representation.

4. That Fake/Genuine recall asymmetry is a fundamental property of deception detection. It may reflect properties of the supplied labels, evaluation population, decision bound
ary, or platform structure.

5. That Regimes C and D constitute a perfect real-time deployment simulation. Some reviewer/platform counters and restaurant-level attributes may be cumulative or static snaps
hots rather than values measured strictly at the review date.

6. That Model C versus Model D isolates the causal value of adding lexical and theory-driven features. The selected family winners also use different algorithms.

7. How classical text models compare with fine-tuned transformer representations. That question is carried forward to Phase 2.

================================================================================================
SECTION 4 — PHASE 2 HANDOFF DECISIONS
================================================================================================

Primary RQ1 classical comparator:
  Model       : Full-origin Model A Logistic Regression
  Regime A F1 : 0.6885 [0.6695, 0.7056]
  Rationale   : Primary RQ1 classical comparator because it is a text-only classical model and is therefore information-equivalent to text-based transformer models.

Strongest overall classical system:
  Model       : Full-origin Model C XGBoost
  Regime A F1 : 0.8893 [0.8763, 0.9014]
  Rationale   : Strongest overall Full-origin classical system when reviewer/platform metadata is permitted. This is retained separately from the information-equivalent RQ1 te
xt comparator.

Validation framework carried into Phase 2:
  regimes               : ['A', 'B', 'C', 'D']
  primary_metric        : Macro-F1
  dependence_unit       : Reviewer cluster
  uncertainty           : Reviewer-cluster bootstrap 95% confidence intervals
  paired_effect         : Paired reviewer-cluster bootstrap ΔMacro-F1 confidence interval
  hypothesis_test       : Reviewer-cluster paired permutation test
  multiplicity          : Holm correction
  Note: Where scientifically appropriate, Phase 2 transformer models should be evaluated under the same frozen evaluation regimes and reviewer-aware uncertainty framework to p
reserve comparability.

✓ Final Phase 1 synthesis outputs saved

================================================================================================
PHASE 1 — CLASSICAL MACHINE LEARNING — COMPLETE AND FROZEN
================================================================================================
✓ Cell 1  : Reproducibility + validation architecture
✓ Cell 2  : Deterministic 6C feature reconstruction
✓ Cell 3  : Pipelines + search spaces
✓ Cell 4A : Training-only reviewer-grouped CV search
✓ Cell 4AR: Model D convergence remediation
✓ Cell 4AS: Selected D-LinearSVC convergence audit
✓ Cell 4B : CV-only family winner selection
✓ Cell 5A : Held-out state audit
✓ Cell 5B : Frozen-model held-out evaluation
✓ Cell 5C : Reviewer-cluster inference + Holm correction
✓ Cell 5D : Final synthesis + Phase 2 handoff
```

```
✓ Nine frozen Phase 1 conclusions recorded
✓ Primary RQ1 comparator frozen
✓ Strongest overall classical system separately frozen
✓ Interpretive limitations explicitly registered
✓ No further Phase 1 optimisation permitted

Primary RQ1 text comparator:
  Full Model A Logistic Regression
  Regime A Macro-F1 = 0.6885 [0.6695, 0.7056]

Strongest overall classical system:
  Full Model C XGBoost
  Regime A Macro-F1 = 0.8893 [0.8763, 0.9014]

PHASE1_FROZEN = True

================================================================================================
PHASE 2 HANDOFF
================================================================================================
0.6885 Macro-F1 is the primary information-equivalent classical text benchmark.
0.8893 Macro-F1 is retained separately as the strongest overall classical benchmark when reviewer/platform metadata is available.
Transformer performance and computational cost will be evaluated against the appropriate frozen classical comparator without altering Phase 1.
```

Phase 2 Tokenizer Length Audit

# PHASE 2A — CELL 1
# Tokenizer Length Audit
#
# Purpose:
# Determine whether max_length = 128 or 256
#
# Frozen decision rule:
# — If ≥95% of Full training reviews fit within 128 tokens
#   INCLUDING special tokens → MAX_LENGTH = 128
# — Otherwise → MAX_LENGTH = 256
#
# STRICT RULES:
# — Label-blind: class labels are never examined
# — No truncation during audit tokenization
# — add_special_tokens=True to match real model input
# — Full clean training corpus only (9,926 reviews)
# — Selected MAX_LENGTH applies identically to:
#       Full origin
#       Historical origin
#       Regimes A/B/C/D
# — No model training
# — No model fitting
# — No held-out access
```

Tokenizing 9,926 reviews...
  truncation=False
  add_special_tokens=True

✓ 9,926 token lengths computed

================================================================================
TOKEN LENGTH DISTRIBUTION — FULL TRAINING CORPUS
================================================================================
  p50 :    57.0 tokens
  p75 :   103.0 tokens
  p90 :   168.0 tokens
  p95 :   214.8 tokens
  p97 :   257.2 tokens
  p99 :   354.8 tokens
  p100:   635.0 tokens

  Mean : 78.72
  SD   : 73.07
  Min  : 1
  Max  : 635

================================================================================
COVERAGE AT CANDIDATE THRESHOLDS
================================================================================
  Reviews ≤128 tokens : 82.70%
  Reviews >128 tokens : 1,717 (17.30%)

  Reviews ≤256 tokens : 96.94%
  Reviews >256 tokens : 304 (3.06%)

================================================================================
FROZEN MAX-LENGTH DECISION
================================================================================
  Decision rule : 128 if ≥95% of Full training reviews fit
  128 coverage  : 82.70%
  256 coverage  : 96.94%

  MAX_LENGTH    : 256
  Rationale     : 82.70% of Full training reviews fit within 128 tokens including special tokens, which is below the pre-specified ≥95% criterion. MAX_LENGTH is therefore froz
en at 256. Coverage at 256 tokens is 96.94%.

================================================================================
TRUNCATION AUDIT
================================================================================
  >128 tokens : 1,717 (17.30%)

PHASE 2A — CELL 2 Reviewer-Grouped Development Split

In [152…

```
# ============================================================
# PHASE 2A — CELL 2
# Reviewer-Grouped Development Split
#
# Purpose:
# Create training-only development splits for epoch selection,
# independently for the Full and Historical training origins.
#
# STRICT RULES:
# — Training data only
# — No held-out regime accessed
# — Approximately 80/20 development split
# — Labels used ONLY for stratification
# — reviewerID used as the grouping variable
# — Zero reviewer overlap between dev-train and dev-val
# — StratifiedGroupKFold(n_splits=5), fixed fold 0
# — Seed = 42
# — Exact reviewer/review assignments saved
# — Split fingerprints saved
# — Splits never regenerated after validation performance is seen

Phase 2A Cell 3B — Historical-origin development fine-tuning
```

Methodological framework

Full-origin development fine-tuning was conducted on 7,949 reviews from the reviewer-grouped development training partition, with epoch selection governed exclusively by development-validation Macro-F1 computed on the held-out 1,977-review development partition. Zero reviewer overlap was maintained between development training and development validation, consistent

with the reviewer-dependence structure established in EDA 5C. No held-out evaluation regime (A, B, C, D) was accessed at any point during this stage. The frozen training configuration — learning rate 2e-5, AdamW optimiser, weight decay 0.01, linear decay scheduler with 10% warmup, gradient clipping at 1.0, physical batch size 16 with gradient accumulation of 2 steps yielding effective batch size 32, FP32 trainable parameters with FP16 autocast — was applied identically across all four development epochs.

Finding 1 — Transient class collapse at epoch 2

At epoch 2, the model predicted all 1,977 development-validation reviews as Genuine, producing Fake F1 = 0.000, Fake recall = 0.000, and Genuine recall = 1.000. This pattern — temporary degeneration to majority-class prediction during early DeBERTa fine-tuning — is documented in the literature on discriminative pre-training instability and reflects the model temporarily abandoning classification signal in favour of the dominant prior. The recovery at epoch 3 (Macro-F1 = 0.606) and continued improvement at epoch 4 confirm this was transient. Epoch 2 was not selected and this behaviour had no effect on the final frozen epoch decision.

Finding 2 — Monotonically improving learning curve with no overfitting evidence

Both training loss and validation loss decreased consistently from epoch 2 onwards. At epoch 4, training loss was 0.6334 and validation loss was 0.6429 — a gap of only 0.0095, indicating the model was not overfitting at the point of selection. Crucially, validation loss had not turned upward at epoch 4, and the validation Macro-F1 trajectory (0.481 → 0.339 → 0.606 → 0.645) showed no plateau. This is evidence that the pre-specified maximum of four epochs was reached before the model converged on this task.

Finding 3 — Selected epoch performance relative to Phase 1 classical baselines

The dev-val Macro-F1 of 0.6446 at epoch 4 is below the Full-origin Model A Logistic Regression CV estimate of 0.6869 from Phase 1. However, this comparison requires careful framing. The development-validation partition specifically excludes reviewers seen during development training, making it a reviewer-disjoint evaluation. Phase 1 CV used reviewer-grouped folds where some reviewer overlap across folds was present, making direct numerical comparison inappropriate. Additionally, the development model was trained on 7,949 reviews rather than the 9,926 that will be used for the full-origin refit. Both factors are expected to produce a lower dev-val estimate than the final held-out performance. The dev-val figure therefore does not yet speak to the transformer-vs-classical comparison, which is deferred to the full-origin refit evaluated on Regimes A and B.

Finding 4 — Methodological constraint: the model had not converged at epoch 4

The absence of overfitting, the declining loss trajectory, and the still-improving Macro-F1 at the maximum epoch collectively indicate that the pre-specified four-epoch ceiling was reached before learning stabilised. This constitutes a methodological constraint that should be documented explicitly in the dissertation. Two responses are defensible: accepting epoch 4 as the frozen selection with acknowledged under-training documented as a limitation; or extending the maximum to six epochs on the basis of observed development evidence before any held-out evaluation, documented transparently as a pre-held-out protocol extension. The dissertation should state explicitly which decision was taken and why, since either choice affects the scientific validity of the transformer-vs-classical comparison.

Finding 5 — Class recall asymmetry at selected epoch

At epoch 4, Genuine recall (0.702) exceeded Fake recall (0.589) — the opposite pattern from Phase 1's behavioural models, which showed Fake recall substantially above Genuine recall. This asymmetry at epoch 4 may reflect that the model has not yet fully calibrated its decision boundary for this task. The pattern warrants examination in the final held-out evaluation to determine whether it persists or resolves with additional training.

BEST_EPOCH_FULL = 4 | Dev-val Macro-F1 = 0.6446

The full-origin refit will initialise DeBERTa-v3-base from pretrained weights and train on all 9,926 Full-origin training reviews for exactly 4 epochs. No development checkpoint is carried forward. The frozen model is then evaluated on Regimes A and B only.

Methodological note: the learning curve at epoch 4 showed no overfitting and continued improvement, consistent with incomplete convergence at the pre-specified epoch ceiling. This is documented as a constraint on the development protocol. Whether to extend to six epochs before the full-origin refit is a pre-held-out decision that must be made and documented before Regime A or B is opened.

What this finding does and does not establish

What it establishes: DeBERTa-v3-base successfully learned a classification signal on the Yelp binary task within four development epochs, recovering from early training instability by epoch 3 and continuing to improve through epoch 4. The development-validation Macro-F1 of 0.6446 represents a lower bound on full-origin refit performance.

What it does not establish: whether the selected epoch represents the model's best achievable performance on this task; whether full-origin refit performance will exceed, match, or fall below the Phase 1 classical text baseline; whether the Fake/Genuine recall pattern at epoch 4 represents the model's stable output distribution or a transient calibration state.

Decision required before Cell 3B

The dissertation must record one of two choices now, before any held-out data is opened:

Option A — Proceed with epoch 4 as frozen. The four-epoch maximum is accepted. Under-training is documented as a methodological limitation. The transformer-vs-classical comparison proceeds with the acknowledged constraint.

Option B — Extend maximum to 6 epochs, rerun Cell 3A, then run Cell 3B with max_epochs = 6. The extension is justified exclusively by the development learning curve — no held-out information. The dissertation states: "Initial development training indicated the model had not converged at the pre-specified four-epoch ceiling, evidenced by continuing improvement in both training loss and validation Macro-F1 with no overfitting. The maximum was therefore extended to six epochs before any held-out evaluation was conducted." This is a legitimate pre-held-out protocol extension, not post-hoc tuning.

Recommended: Option B. The scientific question — whether fine-tuned contextual representations outperform classical text models — cannot be answered fairly with a demonstrably under-trained transformer. An under-trained DeBERTa producing 0.65 Macro-F1 would be an artefact of the training protocol, not a genuine measure of the architecture's capability. Option B produces a more scientifically valid and more publishable comparison.

Development fine-tuning of DeBERTa-v3-base on the Full-origin training partition was conducted over four epochs using a linear learning-rate schedule. The highest development-validation Macro-F1 occurred at epoch 4 (0.6446), which coincided with the pre-specified upper boundary of the development search window. A transient optimisation instability was observed at epoch 2, where the model temporarily predicted all reviews as Genuine before recovering to above-baseline discrimination by epoch 3. Both training loss and validation loss continued to decline through epoch 4 with no evidence of overfitting. While the learning trajectory is consistent with the optimal epoch lying beyond the search window, the four-epoch ceiling was retained without modification to preserve the pre-specified development protocol and avoid adaptive expansion of the optimisation search space based on observed validation performance. The final Full-origin refit trains on 9,926 reviews with approximately 311 optimiser updates per epoch — approximately 25% more than the 249 updates per epoch in development — meaning the frozen epoch selection corresponds to a more extensively optimised final model than the development results alone might suggest.

PHASE 2A CELL 3B — COMPLETE AND FROZEN
================================================================================
✓ Four Historical development epochs evaluated
✓ Selection used DEV_VAL_HIST only
✓ No held-out Regime C/D accessed
✓ No threshold optimisation
✓ No class weighting
✓ No architecture/hyperparameter search
✓ Same protocol as Full-origin Cell 3A
✓ Correct gradient accumulation used
✓ FP32 trainable parameters + FP16 autocast used
✓ Historical-origin best epoch frozen
✓ Development model is NOT the final held-out model

BEST_EPOCH_HIST = 2
PHASE2A_HIST_EPOCH_FROZEN = True

Frozen Full epoch       : 2
Frozen Historical epoch : 2

NEXT AFTER AUDIT:
Phase 2A final refitting — reinitialize from the exact pretrained revision, train on 100% of each training origin for its frozen epoch count, then evaluate on the pre-specifie
d held-out regimes.
```

Initial Historical-origin development training under the pre-specified four-epoch protocol failed to establish meaningful binary discrimination. Training and validation losses remained close to 0.693, while predictions alternated between near-degenerate single-class solutions. Because this failure was identified exclusively on the frozen development partition and before any held-out evaluation, the Historical development optimisation window was extended from four to eight epochs. The model was reinitialised from the same pretrained checkpoint and trained under an otherwise unchanged protocol, with the linear learning-rate schedule recalculated for the expanded optimisation horizon. The original four-epoch run was retained as an optimisation-failure record rather than overwritten.

================================================================================================
PHASE 2A CELL 3C — PRE-HELD-OUT OPTIMISATION REMEDIATION
MAX_EPOCHS = 8 | SYMMETRIC EXTENSION | FULL + HISTORICAL
NO REGIME A/B/C/D ACCESS
================================================================================================

✓ Required frozen Phase 2A objects are present

✓ Protocol-v1 provenance retained
  Cell 3A Full       : best epoch = 4 | dev Macro-F1 = 0.6446
  Cell 3B Historical : best epoch = 3 | dev Macro-F1 = 0.3399
  Mutable live BEST_EPOCH_FULL / BEST_EPOCH_HIST variables are NOT used.

CELL 3C AMENDMENT
  Type     : Adaptive development-stage optimisation amendment
  Decision : Increase the development epoch ceiling from 4 to 8 symmetrically for Full and Historical origins.
  Timing   : Decision fixed before epochs 5-8 were observed and before any held-out Regime A/B/C/D evaluation.
  Ceiling  : Eight epochs is the final development ceiling. No further expansion is permitted after Cell 3C.

================================================================================================
PHASE 2A CELL 3C — COMPLETE AND FROZEN
================================================================================================
  BEST_EPOCH_FULL_3C = 6
  BEST_EPOCH_HIST_3C = 3

✓ Both origins rerun from exact pretrained revision
✓ Independent seed 42 reset for each origin
✓ Exact frozen development partitions verified
✓ Eight epochs observed for both origins
✓ Best epochs selected by dev-val Macro-F1 only
✓ Protocol-v1 Cell 3A and 3B records retained
✓ No threshold tuning
✓ No class weighting
✓ No architecture change
✓ No Regime A/B/C/D access
✓ Eight epochs is FINAL development ceiling
✓ No further epoch-ceiling expansion permitted

PHASE2A_FURTHER_EPOCH_EXTENSION_ALLOWED = False

NEXT — ONLY AFTER CELL 3C RESULTS ARE AUDITED:
Phase 2A Cell 4 — final DeBERTa refits on 100% of each training origin using:
  BEST_EPOCH_FULL_3C
  BEST_EPOCH_HIST_3C

Do NOT evaluate Regime A/B/C/D until Cell 3C output has been reviewed.
```

The pre-held-out symmetric extension to eight epochs produced divergent results across the two training origins. For the Historical-origin, the extended development window resolved the Protocol-v1 optimisation failure: the model achieved a best development Macro-F1 of 0.647 at epoch 3 under the 1,120-update 8-epoch linear schedule. For the Full-origin, the 8-epoch schedule produced optimisation instability, with the model collapsing to near-degenerate all-Fake predictions from epoch 3 onwards and a best development Macro-F1 of only 0.340 at epoch 1. This contrasts markedly with the Protocol-v1 Cell 3A result, in which the Full-origin model under the 996-update 4-epoch schedule achieved a best development Macro-F1 of 0.645 at epoch 4.

The divergence is consistent with a schedule-origin interaction: the 8-epoch linear schedule's more gradual learning-rate decay may have produced an unstable optimisation trajectory for the Full-origin training sample, whereas Protocol-v1's faster decay successfully stabilised learning. Because Cell 3A represents a legitimate governed development experiment producing a successfully trained model, and the 8-epoch schedule failed for the Full-origin before any held-out evaluation, the authoritative Full-origin epoch selection is retained from Cell 3A: BEST_EPOCH_FULL = 4. The authoritative Historical-origin epoch selection is taken from Cell 3C: BEST_EPOCH_HIST = 3. Each origin therefore uses the outcome of its most successful pre-held-out development experiment."

In [17]:
```python
for var_name in [
    "BEST_EPOCH_FULL_3C",
    "BEST_EPOCH_HIST_3C"
]:

```

PHASE 2A CELL 3D—FINAL AUTHORITATIVE GOVERNANCE CONSOLIDATION NO TRAINING | NO MODEL LOADING | NO HELD-OUT ACCESS

In [18]:
```python
# ═══════════════════════════════════════════════════════════
# PHASE 2A — CELL 3D — FINAL MERGED AUTHORITATIVE VERSION
# Development Governance Consolidation
#
```

```
# PURPOSE
# -------
# Permanently consolidate the successful pre-held-out development
# evidence into ONE authoritative origin-specific refit registry.
#
# NO TRAINING
# NO MODEL LOADING
# NO HELD-OUT REGIME A/B/C/D ACCESS
# NO NEW MODEL SELECTION
# NO NEW HYPERPARAMETER TUNING
#
# FINAL AUTHORITATIVE DECISIONS
# -----------------------------
#
# FULL:
#   Source            = Cell 3A Protocol-v1
#   Selected epoch    = 4
#   Scheduler horizon = 4 epochs
#   Dev Macro-F1      = 0.6446
#
# HISTORICAL:
#   Source            = Cell 3C amended development
#   Selected epoch    = 3
#   Scheduler horizon = 8 epochs
#   Dev Macro-F1      = 0.6468
#
# IMPORTANT
# ---------
# Cell 3C Full:
#   BEST_EPOCH_FULL_3C = 1
#   Macro-F1 = 0.3397
# was an optimisation-failure result and MUST NOT be used
# for the final Full-origin refit.
#
# Historical epoch 3 was selected while operating under an
# 8-epoch scheduler. Therefore final Historical refitting uses
# an 8-epoch scheduler horizon but stops after epoch 3.
#
# The final refit uses MORE observations than development.
# Therefore optimizer-step counts and warmup counts are
# recalculated from the final-origin sample sizes.
#
# 8 epochs remains the final development ceiling.
# No further development tuning is permitted.

FINAL TRAINING-ORIGIN SAMPLE SIZES
  Full       : 9,926
  Historical : 5,602

✓ Final-refit schedules recalculated from full training-origin sample sizes

GOVERNANCE INTERPRETATION
The pre-held-out symmetric eight-epoch development amendment produced origin-dependent optimisation outcomes. For the Historical origin, the amended scheduler established meaningful discrimination and epoch 3 was selected by development-validation Macro-F1. For the Full origin, the amended scheduler failed to establish meaningful discrimination; the previously governed Cell 3A Protocol-v1 configuration therefore remains authoritative. The divergent development trajectories are consistent with schedule-dependent optimisation behaviour, but they do not establish a causal mechanism. All authoritative decisions were consolidated before any held-out Regime A/B/C/D evaluation.

TEMPORAL INTERPRETATION CAVEAT
Full and Historical final refits use different validated optimisation schedule horizons (4 epochs versus 8 epochs). Accordingly, eventual held-out performance differences between the two origin-specific pipelines cannot be attributed exclusively to temporal data shift.

```

Following the development-stage optimisation experiments, the final training configurations were consolidated before any held-out evaluation was performed. This step was introduced to ensure that the final DeBERTa refits were based only on successfully governed development results and that no subsequent decisions could be influenced by performance on the held-out evaluation regimes. The exact reviewer-disjoint development partitions established previously were re-verified using stored fingerprints, confirming that the governance decision referred to the same frozen samples used throughout model development. No model training, threshold optimisation, or access to Regimes A–D occurred during this stage.

The development experiments produced different optimisation outcomes for the two training origins. For the Full-origin model, the original four-epoch protocol remained the authoritative configuration. Under this setting, DeBERTa achieved a development Macro-F1 of 0.6446 at epoch 4. By contrast, the subsequent eight-epoch development schedule produced near-degenerate predictions and a best Macro-F1 of only 0.3397, indicating that the amended schedule did not establish meaningful discrimination for the Full-origin sample. The earlier four-epoch configuration was therefore retained. For the Historical-origin model, the opposite pattern was observed. The original four-epoch protocol failed to learn effectively, whereas the amended eight-epoch scheduler produced meaningful class discrimination and achieved its highest development Macro-F1 of 0.6468 at epoch 3. Consequently, epoch 3 under the eight-epoch scheduler was retained for the Historical-origin final refit.

Importantly, the final refit schedules were recalculated using the complete training-origin samples rather than reusing the optimizer-step counts from the smaller development partitions. The Full-origin refit therefore used 9,926 reviews, four training epochs, a four-epoch scheduler horizon, 1,244 total scheduler updates, and 124 warm-up updates. The Historical-origin refit used 5,602 reviews and was trained for three epochs while retaining the eight-epoch scheduler horizon under which epoch 3 had been selected during development. This resulted in an eight-epoch scheduler containing 1,408 total steps and 140 warm-up steps, while only 528 optimizer updates were actually executed before training stopped at the selected third epoch.

Training origin	Authoritative development source	Selected epoch	Dev. Macro-F1	Final N	Scheduler horizon	Warm-up steps
Full	Original four-epoch protocol	**4**	**0.6446**	9,926	4 epochs	124
Historical	Amended eight-epoch protocol	**3**	**0.6468**	5,602	8 epochs	140

This origin-specific consolidation was completed before any held-out prediction or evaluation, thereby preventing test-set information from influencing the final training configuration. The differing schedules should, however, be acknowledged when interpreting later results. Any performance difference between the Full-origin and Historical-origin models cannot be attributed exclusively to temporal distribution shift because the two final pipelines were validated under different optimisation schedules. The divergent development behaviour is consistent with schedule-dependent optimisation effects, although the experiments do not establish a causal mechanism for this interaction.

Prior to held-out evaluation, the final DeBERTa refit configurations were formally consolidated using development-only evidence. The original four-epoch Full-origin protocol was retained because it achieved meaningful discrimination with a development Macro-F1 of 0.6446 at epoch 4, whereas the subsequent eight-epoch schedule produced near-degenerate predictions. Conversely, the Historical-origin model failed under the original four-epoch protocol but learned successfully under the amended eight-epoch scheduler, achieving its highest development Macro-F1 of 0.6468 at epoch 3. Accordingly, the final Full model was trained for four epochs under a four-epoch scheduler, while the Historical model was trained for three epochs under an eight-epoch scheduler horizon. Final optimizer and warm-up step counts were recalculated using the complete training-origin samples (N=9,926 and N=5,602, respectively). All decisions were frozen before any access to the held-out evaluation regimes, preventing test-set information from influencing model selection. Because the two origin-specific pipelines use different validated optimisation schedules, later performance differences are interpreted as differences between origin-specific optimised pipelines rather than as pure causal estimates of temporal distribution shift.

PHASE2A_HELDOUT_ACCESSED = False

NEXT — AFTER THIS OUTPUT IS REVIEWED:
Cell 5 will reload the frozen saved models and generate held-out predictions:
  Full model       → Regimes A and B
  Historical model → Regimes C and D
```

Cell 4 was designed as the final pre-held-out refitting stage in which the two frozen DeBERTa configurations were retrained on 100% of their respective training origins, using only the optimisation decisions established during the preceding development and governance stages. For the Full-origin model, the authoritative Cell 3A configuration was retained, comprising four training epochs

under a four-epoch linear learning-rate scheduler, while the Historical-origin model used the successful Cell 3C configuration, comprising three executed training epochs under an eight-epoch scheduler horizon. Cell 4 correctly verified the frozen Cell 3D registry, confirmed the exact identities of the Full (N = 9,926) and Historical (N = 5,602) training origins using fingerprints, reinitialised each model independently from the exact pinned microsoft/deberta-v3-base revision, and preserved all previously frozen settings including a learning rate of (2\times10^{-5}), weight decay of 0.01, effective batch size of 32, maximum sequence length of 256, seed 42, standard cross-entropy loss, no class weighting, and no threshold tuning. The Full-origin refit completed four epochs with a

steadily decreasing training loss from 0.6813 to 0.5659. However, during the Historical-origin refit, PyTorch issued a warning indicating that the learning-rate scheduler had been advanced when an optimizer step had not been successfully executed. This exposed an implementation weakness in the mixed-precision training loop. Although the code called scaler.step(optimizer) before scheduler.step(), PyTorch's GradScaler may suppress an optimizer update when non-finite gradients are detected; the original Cell 4 implementation nevertheless advanced the scheduler and incremented the optimizer-update counter on every attempted update group. Consequently, the reported total of 528 Historical optimizer updates could not be independently certified as 528

successful parameter updates, and the intended one-to-one correspondence between successful optimizer updates and scheduler progression could not be guaranteed. Importantly, this issue does not imply that the frozen model specification, data, epoch selections, or preceding development results were incorrect, and the decreasing Historical training loss from 0.6948 to 0.6621 indicated that learning was occurring. Nevertheless, because exact reproduction of the frozen learning-rate trajectory is an important part of the experimental protocol, the run cannot be regarded as the authoritative final refit. The same implementation was also used for the Full-origin model; although no warning was observed during that run, the original code did not explicitly record successful

versus AMP-skipped optimizer updates, meaning that the absence of a warning alone is insufficient to provide the same level of auditable assurance required for the final model. Cell 4-R is therefore being conducted as an implementation correction rather than an additional tuning experiment. No hyperparameter, model architecture, dataset, epoch count, scheduler horizon, random seed, or decision rule will be changed, and no held-out Regime A/B/C/D results have been accessed. Instead, Cell 4-R will rerun both origin-specific final refits from the original pretrained checkpoint while explicitly detecting any AMP-skipped optimizer steps, advancing the learning-rate scheduler only when a parameter update is successfully executed, and separately recording attempted update

groups, successful optimizer updates, skipped AMP updates, and scheduler steps. The original Cell 4 run will remain documented as a non-authoritative implementation attempt rather than being silently discarded. This corrective rerun therefore strengthens reproducibility and computational validity without introducing post-hoc model optimisation or held-out information into the training process.

PHASE 2A CELL 4-R—COMPLETE AND FROZEN

In [20]:
```
# ============================================================
# PHASE 2A — CELL 4-R — FINAL AUTHORITATIVE VERSION
# Implementation-Corrected Final DeBERTa Refits
#
# WHY 4-R?
# --------
# Original Cell 4 called scheduler.step() after every attempted
# AMP optimizer update. GradScaler can suppress optimizer.step()
# when non-finite gradients are detected. Therefore Cell 4 could
# advance the LR scheduler without a corresponding parameter
# update.
#
# CORRECTION
# ----------
# Cell 4-R explicitly detects AMP-skipped optimizer updates.
# Scheduler advances ONLY after a successful optimizer update.
#
# Runtime accounting must satisfy:
#
# attempted = successful + AMP-skipped
# scheduler_steps = successful_optimizer_updates
#
# IMPORTANT:
# AMP skips themselves do NOT invalidate the run provided the
# scheduler remains synchronized with successful optimizer steps.
#
# NOTHING ELSE CHANGES:
# — Same frozen Cell 3D governance
# — Same DeBERTa checkpoint and exact revision
# — Same Full/Historical training origins
# — Same epoch selections
# — Same scheduler horizons
# — Same LR, weight decay, batch, grad accumulation and seed
# — Same max length and CE loss
# — No class weighting
# — No threshold tuning
# — NO held-out A/B/C/D access
# — NO predictions
#
# Original Cell 4 remains a non-authoritative implementation
# attempt. Cell 4-R becomes authoritative after successful audit.

Cell 5 will load ONLY the Cell 4-R saved models:
  Full 4-R model       → Regimes A/B
  Historical 4-R model → Regimes C/D
```

Origin	Planned/attempted update groups	Successful optimizer updates	AMP-skipped	Scheduler steps
Full	1,244	**1,238**	**6**	**1,238**
Historical	528	**522**	**6**	**522**

Cell 4-R corrected the mixed-precision training procedure by conditioning learning-rate scheduler advancement on confirmed successful optimizer updates, with changes in the GradScaler scale used to identify AMP-skipped updates. Both origin-specific refits recorded six AMP-skipped update attempts, all occurring within the first two training epochs. Importantly, scheduler advancement

was withheld for every skipped update, maintaining a one-to-one correspondence between successful optimizer updates and learning-rate scheduler steps. For the Full-origin model, 1,238 of 1,244 attempted update groups were successfully executed, and training loss declined consistently from 0.690 in epoch 1 to 0.633 in epoch 4, indicating sustained optimisation across the final refit. For the Historical-origin model, 522 of 528 attempted update groups were successfully executed. Its training loss decreased modestly from 0.691 to 0.687 between epochs 1 and 2 before increasing to 0.694 in epoch 3. The final value is close to $\ln(2)\approx0.693$, corresponding to the cross-entropy loss associated with approximately uniform predictions in a binary classification problem, and therefore

suggests comparatively weak optimisation of the Historical-origin model during the final refit. This trajectory differed from both the original Cell 4 attempt and the successful Cell 3C Historical development trajectory. However, the observed difference cannot be attributed causally to AMP-skipped updates, the learning-rate schedule, or any other individual optimisation mechanism because these factors were not experimentally isolated. No further adjustment was made because the epoch selection and optimisation protocol had been frozen before held-out evaluation. The generalisation performance of the Historical-origin model is therefore assessed exclusively on the pre-specified held-out Regimes C and D in Cell 5.

# ================================================================
# PHASE 2A — CELL 5A-R
# AUTHORITATIVE VERSION
# Exact Frozen Held-Out Regime Reconstruction + Integrity Freeze
#
# PURPOSE
# -------
# The original Phase 1 A/B/C/D DataFrames are no longer live in
# the current Kaggle runtime. This cell reconstructs those exact
# pre-specified evaluation regimes deterministically BEFORE any
# DeBERTa held-out inference.
#
# FROZEN REGIME DEFINITIONS
# -------------------------
# Regime A:
#   Supplied Yelp benchmark test set.
#
# Regime B:
#   Regime A restricted to reviewers absent from the Full-origin
#   training sample.
#
# Regime C:
#   Forward-temporal portion of the clean Full-origin Yelp sample,
#   using the frozen cutoff 2011-01-01.
#
# Regime D:
#   Regime C restricted to reviewers absent from the Historical
#   training origin.
#
# IMPORTANT
# ---------
# Regime B contains:
#   1,833 REVIEW ROWS
#   1,801 UNIQUE REVIEWERS
#
# NO MODEL LOADING
# NO PREDICTIONS
# NO MACRO-F1
# NO THRESHOLDING
# NO TUNING

PHASE 2A CELL 5A-R — EXACT HELD-OUT REGIME RECONSTRUCTION
DATA INTEGRITY ONLY | NO MODEL INFERENCE | NO PERFORMANCE METRICS
================================================================================================

✓ Cell 4-R authoritative state verified
✓ Full and Historical 4-R model artifacts present
✓ No Phase 2A held-out predictions have been generated

Frozen temporal cutoff: 2011-01-01

✓ Supplied Yelp test set reloaded exactly
  N = 2,483

✓ Historical training origin independently reverified against frozen temporal cutoff
  Historical N = 5,602

✓ All four frozen regime sizes verified
✓ All four unique-reviewer counts verified
✓ All four class distributions verified

✓ Nested-regime relationships verified
✓ Regime B ⊂ Regime A
✓ Regime D ⊂ Regime C

✓ Regime B reviewer overlap with Full training = 0

✓ Regime D reviewer overlap with Historical training = 0
✓ Historical training + Regime C exactly partition Full origin by time

✓ Benchmark overlap structure reproduced:
    Shared train/test reviewers = 553

    Test rows from seen reviewers = 650
    Test rows from unseen reviewers = 1,833

    Unique unseen reviewers = 1,801

  Full 4-R model       → Regimes A and B
  Historical 4-R model → Regimes C and D

STOP HERE.
Send the complete output before Cell 5B
```

PHASE 2A CELL 5B — FIRST AUTHORITATIVE HELD-OUT PREDICTIONS FROZEN MODELS | FROZEN REGIMES | NO PERFORMANCE METRICS | NO TUNING

In [23]:
```
# ================================================================
# PHASE 2A — CELL 5B
# FIRST AUTHORITATIVE DeBERTa HELD-OUT PREDICTIONS
#
# ROUTING
# -------
# Full Cell 4-R model       → Regimes A and B
# Historical Cell 4-R model → Regimes C and D
#
```

```
# IMPORTANT
# ---------
# This is the FIRST Phase 2A held-out model access.
#
# This cell:
# ✓ verifies frozen Cell 5A registry
# ✓ reloads exact frozen evaluation CSVs
# ✓ verifies regime SHA-256 fingerprints
# ✓ reloads ONLY saved Cell 4-R models
# ✓ uses frozen max length = 256
# ✓ uses argmax(logits), no threshold tuning
# ✓ saves logits + probabilities + predictions
#
# This cell DOES NOT:
# X calculate Macro-F1
# X calculate accuracy
# X calculate recall/precision
# X calculate confusion matrices
# X calculate bootstrap CIs
# X compare against classical models
# X tune any model or threshold

# PHASE 2A — CELL 5C
# AUTHORITATIVE HELD-OUT METRICS
# + REVIEWER-CLUSTER BOOTSTRAP 95% CONFIDENCE INTERVALS
#
# PURPOSE
# -------
# This is the FIRST authoritative calculation of DeBERTa
# held-out performance.
#
# INPUT
# -----
# ONLY the frozen row-level predictions produced by Cell 5B.
#
# Regime A: Full 4-R
# Regime B: Full 4-R — unseen-reviewer benchmark subset
# Regime C: Historical 4-R — forward temporal
# Regime D: Historical 4-R — forward + unseen reviewers
#
# PRIMARY METRIC
# --------------
# Macro-F1
#
# UNCERTAINTY
# -----------
# Reviewer-cluster percentile bootstrap
# 2,000 attempted replicates
# Reviewer = resampling unit
# 95% confidence interval
# Seed = 42
#
# IMPORTANT
# ---------
# NO model loading
# NO prediction generation
# NO model fitting
# NO threshold tuning
# NO hyperparameter changes
```

```python
# NO classical-model comparison
# NO H1 decision
#
# Cell 5D will perform the frozen paired transformer-vs-classical
# comparisons and formally assess RQ1 / H1.

PHASE 2A—CELL 5C AUTHORITATIVE HELD-OUT METRICS REVIEWER-CLUSTER BOOTSTRAP 95% CONFIDENCE INTERVALS

Phase 2A evaluated the frozen DeBERTa-v3-base classifiers under the same four held-out regimes used for the classical baselines. The Full-origin model achieved a Macro-F1 of 0.639 on Regime A (95% reviewer-cluster CI [0.620, 0.657]) and 0.609 on the unseen-reviewer Regime B ([0.586, 0.630]). Performance therefore declined descriptively by 0.030 when evaluation was restricted to previously unseen reviewers. Class-specific results remained non-degenerate in both regimes, indicating that the Full-origin model had learned meaningful, albeit modest, textual discrimination.

The Historical-origin model produced a qualitatively different result. It classified every observation as Filtered/Suspicious in both forward Regimes C and D. Genuine recall was therefore 0.000 and Fake recall 1.000 in both regimes, producing Macro-F1 values of 0.326 ([0.318, 0.333]) and 0.340 ([0.332, 0.347]) respectively. This constitutes complete one-class prediction collapse rather than ordinary deterioration in classification accuracy. Consequently, Regimes C and D cannot provide a clean estimate of temporal generalisation performance because the final Historical-origin classifier did not retain usable class discrimination.

The Historical collapse is consistent with the optimisation warning already visible in the authoritative Cell 4-R refit, whose training loss changed only marginally from 0.691 to 0.687 before increasing to 0.694 in epoch 3. However, the available experiments do not identify a single causal mechanism for this failure. In particular, the six AMP-skipped update attempts, the learning-rate schedule, the smaller Historical training sample and other optimisation factors were not independently manipulated. The result should therefore be reported as an observed training failure associated with an unstable final optimisation trajectory, rather than attributed specifically to AMP skipping.

For the Full-origin comparison, DeBERTa's Regime A Macro-F1 of 0.639 was 0.0495 below the frozen information-equivalent TF-IDF Logistic Regression comparator (0.6885). Relative to the strongest overall classical system, XGBoost using reviewer behavioural variables (0.8893), the difference was −0.2503. Thus, the proposed ≥0.10 Macro-F1 improvement was not achieved under either comparison. Formal conclusions regarding the statistical reliability of these differences are reserved for the pre-specified paired reviewer-cluster analysis in Cell 5D.

The Full-origin underperformance is compatible with the broader Phase 1 finding that Yelp's filtering labels were considerably more predictable from reviewer behavioural metadata than from review text alone. This suggests that increasing textual model capacity does not necessarily compensate for the absence of account-level signals strongly associated with the platform's filtering decisions. This interpretation should remain dataset-specific because the Yelp labels represent Filtered/Suspicious status rather than unambiguous ground truth for human deception.

# ================================================================
# PHASE 2A — CELL 5D-R3 — FINAL IMPROVED VERSION
#
# DETERMINISTIC PHASE 1 CLASSICAL WINNER RECOVERY
# TRAINING-ONLY REPRODUCIBILITY REPLAY
#
# PURPOSE
# -------
# Recover ONLY the four frozen Phase 1 classical estimators required
```

```
# for the Phase 2A transformer-vs-classical comparison:
#
#   1. Full_A_LR
#   2. Full_C_XGBoost
#   3. Hist_A_LinearSVC
#   4. Hist_C_XGBoost
#
# WHY THIS IS NOT NEW MODEL SELECTION
# -----------------------------------
# The following were already frozen in Phase 1 and recovered verbatim
# from the surviving notebook source in Cell 5D-R2:
#
#   • algorithms
#   • features
#   • TF-IDF specification
#   • hyperparameter grids
#   • reviewer-grouped CV strategy
#   • random seed
#   • training origins
#   • primary metric
#   • four winning search keys required for Phase 2A
#
# We are replaying the historical frozen searches only because the
# original fitted estimator objects / row-prediction file were lost
# when the earlier Kaggle runtime was cleared.
#
# CRITICAL ACCEPTANCE RULE
# ------------------------
# Each reconstructed search MUST reproduce its already-frozen Phase 1
# best CV Macro-F1 to SIX decimal places.
#
# If even ONE model fails:
#
#       STOP.
#
#       NO recovered estimator is accepted as authoritative.
#       NO held-out classical prediction is permitted.
#       NO Phase 2 paired inference is permitted.
#
# STRICT BOUNDARY
# ---------------
# THIS CELL:
#   ✓ reads Full / Historical training origins
#   ✓ performs frozen Phase 1 CV replay
#   ✓ refits the already-selected winner through GridSearchCV(refit=True)
#   ✓ saves recovered fitted estimators AFTER all four CV checks pass
#
# THIS CELL DOES NOT:
#   ✗ load Regime A
#   ✗ load Regime B
#   ✗ load Regime C
#   ✗ load Regime D
#   ✗ generate classical held-out predictions
#   ✗ compare against DeBERTa predictions
#   ✗ calculate paired bootstrap effects
#   ✗ calculate permutation p-values
#   ✗ assess H1
#
# R4 will recover the missing Phase 1 row-level held-out predictions
# only AFTER this cell passes completely.

```
# ============================================================================
# PHASE 2A — CELL 5D-R3 — AUTHORITATIVE CORRECTED FINAL VERSION
#
# CLASSICAL PHASE 1 ARTIFACT RECOVERY
# TRAINING-ONLY REPLAY | NO HELD-OUT PREDICTIONS
#
# RECOVERY POLICY
# ---------------
# Full_A_LR
#   → exact six-decimal Phase 1 CV reproduction REQUIRED
#
# Full_C_XGBoost
#   → exact six-decimal Phase 1 CV reproduction REQUIRED
#
# Hist_A_LinearSVC
#   → exact historical CV replay is NOT currently reproducible:
#
#       Historical reconstruction record : 0.679478
#       Surviving Phase 1 report         : 0.6795
#       Current controlled replay        : 0.680174434
#       Difference                       : +0.000696434
#
#     The following have already been independently established:
#       ✓ exact Historical sample membership
#       ✓ exact Historical row order
#       ✓ exact text
#       ✓ exact labels
#       ✓ exact reviewer grouping
#       ✓ exact TF-IDF specification
#       ✓ exact LinearSVC search grid
#       ✓ same winning hyperparameter configuration
#
#     Therefore this estimator is retained only as a:
#
#       PROVISIONAL_NON_EXACT_CV_REPLAY
#
#     It is NOT authoritative for Phase 2 inference.
#
#     R4 MUST reproduce the historical held-out confusion matrices
#     exactly before Hist_A_LinearSVC predictions can be accepted.
#
# Hist_C_XGBoost
#   → exact six-decimal Phase 1 CV reproduction REQUIRED
#
# IMPORTANT
# ---------
# R3 DOES NOT:
#   X load Regime A/B/C/D
#   X make held-out predictions
#   X calculate held-out performance
#   X compare with DeBERTa
#   X conduct bootstrap/permutation inference
#   X assess H1
#
# R3 DOES:
#   ✓ verify source provenance
#   ✓ verify training-origin provenance
#   ✓ reconstruct account_age_days if required
#   ✓ lock critical software versions
#   ✓ freeze/audit exact CV fold membership
#   ✓ replay only the four already-selected Phase 1 comparators
#   ✓ serialize recovery-candidate fitted estimators
#   ✓ save fold assignments, hyperparameters and CV candidate tables
#   ✓ hash every recovery artifact
#   ✓ explicitly mark Hist_A as provisional
#
# DO NOT MODIFY A FAILED ASSERTION JUST TO MAKE THIS CELL PASS.

```
# ============================================================================
# PHASE 2A — CELL 5D-R4 — FINAL CLASSICAL HELD-OUT PREDICTION RECOVERY
#
# PURPOSE
# -------
# Use ONLY the frozen R3 recovery-candidate estimators to reconstruct
# the row-level Phase 1 classical predictions required for Cell 5D.
#
# DECISIVE ACCEPTANCE RULE
# ------------------------
# Every routed model × regime evaluation must reproduce the ORIGINAL
# Phase 1 held-out confusion matrix EXACTLY.
#
# Required routes:
#
#   Regime A → Full_A_LR,        Full_C_XGBoost
#   Regime B → Full_A_LR,        Full_C_XGBoost
#   Regime C → Hist_A_LinearSVC, Hist_C_XGBoost
#   Regime D → Hist_A_LinearSVC, Hist_C_XGBoost
#
# Hist_A_LinearSVC remains provisional until BOTH:
#
#   C: TN=1386 FP=851 FN=569 TP=1518
#   D: TN=1172 FP=774 FN=555 TP=1507
#
# reproduce EXACTLY.
#
# THIS CELL:
#   ✓ accesses frozen held-out regimes
#   ✓ generates classical recovery predictions
#   ✓ verifies exact historical confusion matrices
#   ✓ saves row-level predictions ONLY after every gate passes
#
# THIS CELL DOES NOT:
#   X compare classical models with DeBERTa
#   X run bootstrap/permutation inference
#   X apply Holm correction
#   X assess H1
#   X tune/refit/reselect any model
#
# IMPORTANT:
# If any exact confusion-matrix assertion fails:
# STOP. Do not modify the historical target.

# ==============================================================================
# PHASE 2A — CELL 5D-R4B SESSION RESTORE
#
# PURPOSE
# -------
# Restore ONLY the objects required by R4B after a Kaggle/kernel restart.
#
# This cell:
#   ✓ loads the four frozen R3 classical models
#   ✓ loads and verifies Regimes A/B/C/D
#   ✓ reconstructs deterministic behavioural feature sources
#   ✓ restores ROUTES
#   ✓ restores historical confusion/F1 references
#   ✓ restores get_regime_X()
#
# This cell DOES NOT:
#   X fit any model
#   X tune any model
#   X generate inference
#   X compare against DeBERTa
#   X assess H1
# ==============================================================================

Run R4 only through setup/model-loading sections first.
```

Of eight required classical model–regime reconstruction checks, five reproduced the historical Phase 1 confusion matrices exactly. The three non-exact checks involved the linear text classifiers and

differed by only a small number of classifications, while retaining virtually identical aggregate Macro-F1. Because the original row-level Phase 1 prediction artifact was unavailable, no predictions were manually altered to reproduce historical aggregate counts. The deterministic reconstructed predictions were retained and explicitly flagged as non-bitwise reconstructions. All XGBoost comparator predictions, including the strongest classical baseline used for the primary H1 assessment, reproduced exactly.

Five of eight model–regime reconstruction routes reproduced the original held-out confusion matrices exactly. Three routes showed small numerical divergences (total absolute cell differences of 2, 4, and 6 predictions respectively out of sample sizes of 2,483–4,324), consistent with implementation-sensitive convergence behaviour in iterative optimization. The direction and magnitude of all scientific conclusions are robust to these differences.

In [1]:
```
# ═══════════════════════════════════════════════════════════════════════════
# PHASE 2A — CELL 5D-R4C — FINAL CLASSICAL RECONSTRUCTION ACCEPTANCE & FREEZE
#
# PURPOSE
# -------
# Freeze the most faithful recoverable Phase 1 classical row-level predictions.
#
# GOVERNANCE PRINCIPLE
# --------------------
# Five model × regime routes reproduce the original Phase 1 confusion
# matrices EXACTLY.
#
# Three linear-text routes do not reproduce bit-for-bit, but their controlled
# deterministic replay has now been fully diagnosed:
#
#   Full_A_LR        — A : historical (825,387,386,885)
#                          replay     (824,388,386,885)
#
#   Hist_A_LinearSVC — C : historical (1386,851,569,1518)
#                          replay     (1387,850,570,1517)
#
#   Hist_A_LinearSVC — D : historical (1172,774,555,1507)
#                          replay     (1174,772,556,1506)
#
# These three are retained as:
#
#       NON_EXACT_NUMERICAL_RECONSTRUCTION
#
# NO historical prediction is manually changed.
# NO arbitrary tolerance threshold is introduced.
#
# Instead, the exact R4B reconstruction signatures above are now frozen.
# Any FUTURE run must reproduce these signatures exactly.
#
# THIS CELL:
#   ✓ verifies all eight current reconstruction signatures
#   ✓ quantifies historical divergence
#   ✓ saves current row-level reconstructed predictions
#   ✓ explicitly labels exact vs non-exact provenance
#   ✓ freezes a registry + SHA
#
# THIS CELL DOES NOT:
#   ✗ refit models
#   ✗ tune models
#   ✗ change winners
#   ✗ alter predictions
#   ✗ compare against DeBERTa
#   ✗ run bootstrap/permutation inference
#   ✗ assess H1

Dissertation — Phase 2A RS-1 Historical-Origin Final Recovery Refit

Stage: RS-4H — one-time Historical-origin recovery refit only.

Run this notebook in a **fresh Kaggle Tesla T4 runtime**, after the Full RS-4F artifact ZIP has been downloaded and independently SHA-256 verified.

The verified Full artifact is frozen and must never be retrained.

Historical recovery contract

- Historical N = **5,602**
- Physical batch = **2**
- Gradient accumulation = **16**
- Effective batch = **32**
- Execute **3 epochs only**
- Optimizer updates / epoch = **176**
- Executed optimizer updates = **528**
- Scheduler horizon = **8 epochs / 1,408 steps**
- Warmup = **140**
- FP32 only; no autocast; no GradScaler
- No validation and no held-out inference during refit

Critical rule: train 3 epochs while retaining the frozen 8-epoch scheduler trajectory. A 3-epoch scheduler is prohibited.

Previously verified provenance:

- Full RS-4F ZIP SHA-256: `12962bd779ab9523d24736af2c68823ac66d41c56334261d7341d31991c8e545`
- Cell 3D authoritative registry SHA-256: `8848587a2dd24976710a3f7a30514ed3a55f24228178f470c98cd64a1645c118`
- RS-2 protocol SHA-256: `a6c2ae70b0b348544017ebd8aeda0ad8ecb95a54fc4c571319090d6a4e29dc9f`
- RS-3S smoke SHA-256: `fd8de543e69e7810ec5cf0b7b6b0c1b9a0cadd2bb7717af0a73af2f8de451b1d`
- RS-3S initial whole-model SHA-256: `c66e8175c2e9f031da9bfd766479b4fceed74caa1c47888bf0cdc0f9d15b01d1`
- RS-3P memory-contract SHA-256: `519114f014063354336294ae6a96d1385974d355d9f4169739ef78c9223a5b53`

Run order

Run **H0** → **H1** → **H2** → **H3** only.

# ============================================================================
# H4 — RS-1 HISTORICAL FROZEN HELD-OUT INFERENCE: REGIMES C + D
# RUN ONCE, ONLY AFTER RS-4H ARTIFACT HAS BEEN EXTERNALLY SHA-256 VERIFIED
#
# This cell:
#   1) reconstructs and fingerprints C/D from the already-audited train origin,
#   2) verifies the frozen RS-4H artifact byte-for-byte,
#   3) RELOADS the saved model (does not use the live training model),
#   4) predicts C/D once with argmax(logits), no tuning,
#   5) saves row-level logits/probabilities and metrics,
#   6) creates a hashed, downloadable prediction ZIP.
#
# It does NOT train, refit, tune thresholds, or select a model.
